Abstract:

Purpose: The aim of this study is applying a new method for Industrial robotic system selection.

Design/methodology/approach: In this paper, the weights of each criterion are calculated using fuzzy Shannon’s Entropy. After that, fuzzy TOPSIS is utilized to rank the alternatives. After that we compare the result of Fuzzy TOPSIS with Fuzzy VIKOR method. Then we select the best Industrial Robotic System based on these results.

Findings: The outcome of this research is ranking and selecting industrial robotic systems with the help of Fuzzy Shannon’s Entropy and Fuzzy TOPSIS techniques.

Originality/value: This paper offers a new integrated method for industrial robotic system selection.

Keywords: entropy, TOPSIS, fuzzy set, robotic systems

1 Introduction

Recent developments in information technology and engineering sciences have been the main reason for the increased utilization of robots in a variety of advanced
manufacturing facilities. Robots with vastly different capabilities and specifications are available for a wide range of applications (Rao, 2007). The selection of robots to suit a particular application and production environment from among the large number available in the market has become a difficult task. Various aspects such as product design, production system, and economics, need to be considered before a suitable robot can be selected. The selection problem is particularly relevant in view of the likely lack of experience of prospective users in employing a robot. Indeed, robots are still a new concept in industry as a whole, and so it is not unusual for an industry to be a first-time robot purchaser (Rao, 2007). Many precision-based methods for robot selection have been developed to date. Boubekri, Sahoui and Lakrib (1991) developed an expert system for industrial robot selection considering functional, organizational, and economical attributes in the selection process. Wang, Singh and Huang (1991) presented a decision support system that applies a fuzzy set method for robot selection. The objective attributes were evaluated via marginal value functions while the subjective attributes were evaluated via fuzzy set membership function. Data from both evaluations were finally processed such that a fuzzy set decision vector was obtained. However, the fuzzy method presented is a complicated one, and requires more computation. Booth, Khouja and Hu (1992) proposed a decision model for the robot selection problem using both Mahalanobis distance analysis, i.e., a multivariate distance measure, and principal-components analysis. Liang and Wang (1993) proposed a robot selection algorithm by combing the concepts of fuzzy set theory and hierarchical structure analysis. The algorithm was used to aggregate decision makers’ fuzzy assessments about robot selection attributes weightings, and to obtain fuzzy suitability indices. The suitability ratings were then ranked to select the most suitable robot. Khouja and Offodile (1994) reviewed the literature on industrial robots selection problems and provided directions for future research. Khouja (1995) presented a two-phase robot selection model that involved the application of data envelopment analysis (DEA) in the first phase, and a multi-attribute decision-making model in the second phase. The rest of the paper is organized as follows: The following section presents a concise treatment of the basic concepts of fuzzy set theory. Section 3 presents the methodology. The application of the proposed method is addressed in Section 4. Finally, conclusions are provided in Section 5.

2 Fuzzy sets and fuzzy numbers

Fuzzy set theory, which was introduced by Zadeh (1965) to deal with problems in which a source of vagueness is involved, has been utilized for incorporating imprecise data into the decision framework. A fuzzy set \( \tilde{A} \) can be defined
mathematically by a membership function $\mu_{\tilde{A}}(x)$, which assigns each element $x$ in the universe of discourse $X$ a real number in the interval $[0,1]$. A triangular fuzzy number $\tilde{A}$ can be defined by a triplet $(a, b, c)$ as illustrated in Figure 1.

![Fig 1. A triangular fuzzy number $\tilde{A}$](image)

The membership function $\mu_{\tilde{A}}(x)$ is defined as

$$\mu_{\tilde{A}}(x) = \begin{cases} \frac{x-a}{b-a} & a \leq x \leq b \\ \frac{c-x}{c-b} & b \leq x \leq c \\ 0 & \text{otherwise} \end{cases}$$

Basic arithmetic operations on triangular fuzzy numbers $A_1 = (a_1, b_1, c_1)$, where $a_1 \leq b_1 \leq c_1$, and $A_2 = (a_2, b_2, c_2)$, where $a_2 \leq b_2 \leq c_2$, can be shown as follows:

**Addition:** $A_1 \oplus A_2 = (a_1 + a_2, b_1 + b_2, c_1 + c_2)$

**Subtraction:** $A_1 \ominus A_2 = (a_1 - b_2, b_1 - b_2, c_1 - c_2)$

**Multiplication:** if $k$ is a scalar

$$k \odot A_1 = (k a_1, k b_1, k c_1), \quad k > 0$$

$$k \odot A_2 = \begin{cases} (k a_2, k b_2, k c_2) & , \text{if } a_1 \geq 0, a_2 \geq 0 \\ (k c_2, k b_2, k a_2) & , \text{if } a_1 < 0, a_2 \geq 0 \\ (k a_2, k b_2, k c_2) & , \text{if } a_1 \geq 0, a_2 < 0 \end{cases}$$

**Division:** $A_1 \oslash A_2 \approx \left( \frac{a_1}{b_2}, \frac{b_1}{b_2}, \frac{c_1}{c_2} \right)$, if $a_1 \geq 0, a_2 \geq 0$

Although multiplication and division operations on triangular fuzzy numbers do not necessarily yield a triangular fuzzy number, triangular fuzzy number approximations can be used for many practical applications (Kaufmann & Gupta, 1988). Triangular fuzzy numbers are appropriate for quantifying the vague information about most decision problems including personnel selection (e.g. rating for creativity, personality, leadership, etc.). The primary reason for using triangular fuzzy numbers can be stated as their intuitive and computational-efficient representation (Karsak, 2002). A linguistic variable is defined as a variable whose
values are not numbers, but words or sentences in natural or artificial language. The concept of a linguistic variable appears as a useful means for providing approximate characterization of phenomena that are too complex or ill-defined to be described in conventional quantitative terms (Zadeh, 1975).

3 Research methodology

In this paper, the weights of each criterion are calculated using fuzzy Shannon’s Entropy. After that, fuzzy TOPSIS is utilized to rank the alternatives. In this paper, Fuzzy VIKOR method is used to compare the result of Fuzzy TOPSIS. Finally, we select the best Industrial Robotic System based on these results.

3.1 The fuzzy TOPSIS method

TOPSIS views a MADM problem with m alternatives as a geometric system with m points in the n-dimensional space. The method is based on the concept that the chosen alternative should have the shortest distance from the positive-ideal solution and the longest distance from the negative-ideal solution. TOPSIS defines an index called similarity to the positive-ideal solution and the remoteness from the negative-ideal solution. Then the method chooses an alternative with the maximum similarity to the positive-ideal solution (Wang & Chang, 2007). It is often difficult for a decision-maker to assign a precise performance rating to an alternative for the attributes under consideration. The merit of using a fuzzy approach is to assign the relative importance of attributes using fuzzy numbers instead of precise numbers. This section extends the TOPSIS to the fuzzy environment (Yang & Hung, 2007). This method is particularly suitable for solving the group decision-making problem under fuzzy environment. We briefly review the rationale of fuzzy theory before the development of fuzzy TOPSIS. The mathematics concept borrowed from Ashtiani, Haghhighrad, Makui and Montazer (2009), (Büyüközkan, Feyziog-Lu &Nebol, 2007) and (Wang & Chang, 2007).

**Step 1: Determine the weighting of evaluation criteria**

A systematic approach to extend the TOPSIS is proposed to selecting an Industrial Robotic System under a fuzzy environment in this section. In order to perform a pairwise comparison among the parameters, a linguistic scale has been developed. Our scale is depicted in Figure 2 and the corresponding explanations are provided in Table 1. We have used five main linguistic terms to compare the criteria: “equal importance”, “moderate importance”, “strong importance”, “very strong importance” and “demonstrated importance”. We have also considered their
reciprocals: “equal unimportance”, “moderate unimportance”, “strong unimportance”, “very strong unimportance” and “demonstrated unimportance”. For instance, if criterion A is evaluated “strongly important” than criterion B, then this answer means that criterion B is “strongly unimportant” than criterion A.

Figure 2. Membership functions of triangular fuzzy numbers corresponding to the linguistic scale

<td>(7, 9, 11)</td>
<td>(1/11, 1/9, 1/7)</td>
</tr>
</tbody>
</table>

Table 1. The linguistic scale and corresponding triangular fuzzy numbers

Step 2: Construct the fuzzy decision matrix

\[
M(x) = \frac{1}{\alpha} (x_1^*, x_2^* + \ldots + x_n^*)
\]

where \(x_i^*\) is the rating of alternative \(A_i\) with respect to criterion \(C_j\) evaluated by expert and

\[
x_i^* = (x_i^0, x_i^1, x_i^2)
\]
Step 3: Normalize the fuzzy decision matrix

The normalized fuzzy decision matrix denoted by \( \tilde{R} \) is shown as following formula:

\[
\tilde{R} = [\tilde{r}_{ij}]_{m \times n}, \quad i = 1,2,...,m; \quad j = 1,2,...,n
\]  

(7)

Then the normalization process can be performed by following formula:

\[
\tilde{r}_{ij} = \left( \frac{\tilde{a}_{ij}}{\tilde{b}_{ij}}, \frac{\tilde{b}_{ij}}{\tilde{c}_{ij}}, \frac{\tilde{c}_{ij}}{\tilde{a}_{ij}} \right) c_i = \max c_i
\]

Where

The normalized \( \tilde{r}_{ij} \) are still triangular fuzzy numbers. For trapezoidal fuzzy numbers, the normalization process can be conducted in the same way. The weighted fuzzy normalized decision matrix is shown as following matrix \( \tilde{V} \):

\[
\tilde{V} = [\tilde{v}_{ij}]_{m \times n}, \quad i = 1,2,...,m; \quad j = 1,2,...,n
\]

(8)

\[
\tilde{v}_{ij} = \tilde{r}_{ij} \otimes \tilde{c}_j
\]

(9)

Step 4: Determine the fuzzy positive-ideal solution (FPIS) and fuzzy negative-ideal solution (FNIS)

According to the weighted normalized fuzzy decision matrix, we know that the elements \( \tilde{v}_{ij} \) are normalized positive TFNs and their ranges belong to the closed interval \([0, 1]\). Then, we can define the FPIS \( A^+ \) and FNIS \( A^- \) as following formula:

\[
A^+ = (\tilde{v}_{i+}^+, \tilde{v}_{i+}^2, ..., \tilde{v}_{i+}^n)
\]

(10)

\[
A^- = (\tilde{v}_{i-}^+, \tilde{v}_{i-}^2, ..., \tilde{v}_{i-}^n)
\]

(11)

where \( \tilde{v}_{ij}^+ = (1,1,1) \) and \( \tilde{v}_{ij}^- = (0,0,0) \) \( j = 1,2,...,n \)

Step 5: Calculate the distance of each alternative from FPIS and FNIS

The distances \( (d_i^+, d_i^-) \) of each alternative \( A^+ \) from and \( A^- \) can be currently calculated by the area compensation method.

\[
d_i^+ = \sum_{j=1}^{n} d(\tilde{r}_{ij}, \tilde{v}_{ij}^+) \quad i = 1,2,...,m \quad j = 1,2,...,n
\]

(12)

\[
d_i^- = \sum_{j=1}^{n} d(\tilde{r}_{ij}, \tilde{v}_{ij}^-) \quad i = 1,2,...,m \quad j = 1,2,...,n
\]

(13)
Step 6: Obtain the closeness coefficient and rank the order of alternatives

The CC\(_i\) is defined to determine the ranking order of all alternatives once the \(d_i^+\) and \(d_i^-\) of each alternative have been calculated. Calculate similarities to ideal solution. This step solves the similarities to an ideal solution by formula:

\[
CC_i = \frac{\frac{1}{d_i^+}}{\frac{1}{d_i^+} + \frac{1}{d_i^-}} \quad i = 1, 2, ..., m
\]  
(14)

According to the CC\(_i\), we can determine the ranking order of all alternatives and select the best one from among a set of feasible alternatives.

3.2 Fuzzy Shannon’s entropy based on \(\alpha\)-level sets

Hosseinzadeh, Lotfi and Fallahnejad (2010) extend the Shannon entropy for the imprecise data, especially interval and fuzzy data cases. In this paper we obtain the weights of criteria based on their method. The steps of fuzzy Shannon’s Entropy explained as follow (Hosseinzadeh et al., 2010):

**Step 1:** transforming fuzzy data into interval data by using the \(\alpha\)-level sets:

The \(\alpha\)-level set of a fuzzy variable \(\tilde{x}_{ij}\) is defined by a set of elements that belong to the fuzzy variable \(\tilde{x}_{ij}\) with membership of at least \(\alpha\) i.e., \(\tilde{x}_{ij}^\alpha = \{x_{ij} \in R | \mu_{\tilde{x}_{ij}}(x_{ij}) \geq \alpha\}\).

The \(\alpha\)-level set can also be expressed in the following interval form:

\[
[(\tilde{x}_{ij}^\alpha)^-, (\tilde{x}_{ij}^\alpha)^+] = [\min_{x_{ij}} | x_{ij} \in R | \mu_{\tilde{x}_{ij}}(x_{ij}) \geq \alpha], \max_{x_{ij}} | x_{ij} \in R | \mu_{\tilde{x}_{ij}}(x_{ij}) \geq \alpha]
\]  
(15)

where \(0 < \alpha \leq 1\). By setting different levels of confidence, namely \(1-\alpha\), fuzzy data are accordingly transformed into different \(\alpha\)-level sets \{(\tilde{x}_{ij})_\alpha | 0 < \alpha \leq 1\}, which are all intervals.

**Step 2:** The normalized values \(p_{ij}^\prime\) and \(p_{ij}^\prime\prime\) are calculated as:

\[p_{ij}^\prime = \frac{x_{ij}^0}{\sum_{j=1}^{n} x_{ij}^0}, p_{ij}^\prime\prime = \frac{x_{ij}^\alpha}{\sum_{j=1}^{n} x_{ij}^\alpha}, j = 1, ..., m, i = 1, ..., n\]  
(16)

**Step 3:** Lower bound \(h_i^\prime\) and upper bound \(h_i^\prime\prime\) of interval entropy can be obtained by:

\[
h_i^\prime = \min \{ - \sum_{j=1}^{n} p_{ij}^\prime \cdot \ln p_{ij}^\prime, - \sum_{j=1}^{n} p_{ij}^\prime\prime \cdot \ln p_{ij}^\prime\prime \}, i = 1, ..., n \quad \text{and}
\]
\[
h_i^\prime\prime = \max \{ - \sum_{j=1}^{n} p_{ij}^\prime \cdot \ln p_{ij}^\prime, - \sum_{j=1}^{n} p_{ij}^\prime\prime \cdot \ln p_{ij}^\prime\prime \}, i = 1, ..., n
\]  
(17)

where \(h_0\) is equal to \((\ln m)^{-1}\), and \(p_{ij}^\prime \cdot \ln p_{ij}^\prime\) or \(p_{ij}^\prime\prime \cdot \ln p_{ij}^\prime\prime\) is defined as 0 if \(p_{ij}^\prime = 0\) or \(p_{ij}^\prime\prime = 0\).
**Step 4:** Set the lower and the upper bound of the interval of diversification \(d_i^l\) and \(d_i^u\) as the degree of diversification as follows:

\[
d_i^l = 1 - \delta_i^u, \quad d_i^u = 1 - \delta_i^l, \quad i=1,\ldots,n
\]

(18)

**Step 5:** Set \(w_i^l, i=1,\ldots,n\) as the lower and upper bound of interval weight of attribute \(i\).

### 4 Numerical example

In this section, we demonstrate the application of this method by numerical example. Through the literature investigation and studying other papers that are related to robotic system selection, finally ten criteria are selected. These criteria include purchasing cost (\(C_1\)), Maintenance Cost (\(C_2\)), Training Cost (\(C_3\)), Labor Cost (\(C_4\)), Repeatability error (\(C_5\)), Speed (\(C_6\)), Load carrying capacity (\(C_7\)), Man-machine interface (\(C_8\)), Memory capacity (\(C_9\)) and accuracy (\(C_{10}\)). In addition, there are four alternatives include \(A_1\), \(A_2\), \(A_3\) and \(A_4\).

#### 4.1 Fuzzy Shannon’s Entropy

In fuzzy Shannon’s Entropy, firstly, the criteria and alternatives’ importance weights must be compared. Afterwards, the comparisons about the criteria and alternatives, and the weight calculation need to be made. Thus, the evaluation of the criteria according to the main goal and the evaluation of the alternatives for these criteria must be realized. Then, after all these evaluation procedure, the weights of the alternatives can be calculated. In the second step, these weights are used to Fuzzy TOPSIS calculation for the final evaluation. The aggregate decision matrix for Shannon’s Entropy can be seen from Table 2.

5 Conclusion

Industrial robots have been increasingly used by many manufacturing firms in different industries. Although the number of robot manufacturers is also increasing with many alternative ranges of robots, potential end users are faced with many factors in the evaluation of the industrial robotic systems. A two-step fuzzy Shannon’s Entropy and fuzzy TOPSIS methodology is structured here that fuzzy TOPSIS uses fuzzy Shannon’s Entropy result weights as input weights. Then a numerical example is presented to show applicability and performance of the methodology. After that the results of fuzzy TOPSIS compare with Fuzzy VIKOR method. It can be said that using linguistic variables makes the evaluation process more realistic. Because evaluation is not an exact process and has fuzziness in its body. Here, the usage of fuzzy Shannon’s Entropy weights in fuzzy TOPSIS makes the application more realistic and reliable. It is clear that the selection of an industrial robotic system is a difficult. However, the developed fuzzy method seems to be usable for the solution of this problem.
