Abstract—GILABVIR (Group d’Interès en Laboratoris Virtuals i Remots) is a recently created Virtual and Remote Laboratory Group of Interest at the UPC (Universitat Politècnica de Catalunya) and it is integrated in a more general teaching innovation project: RIMA [1], [2]. RIMA has been developed to promote research on the use of innovative learning methodologies applied to engineering education and it was specially created to assess in the new European higher education adaptation process.

Keywords—Generic skill, digital campus, software platform, laboratory experiment.

I. INTRODUCTION

The GILABVIR Group is formed by high education faculty members who are involved within different laboratory courses, all of them characterized by the use of real and simulated experiments accessed through the Moodle-based UPC digital campus platform (ATENEA). The experiments in the different laboratory courses usually follow the next three steps sequence: 1.- The student designs the experiment and configures the parameters on-line, either a distance or in the computer classroom. 2.- The experiment is executed. 3.- The different results (numerical, graphical, in aging, etc.) are displayed and optionally recorded at the ATENEA server.

Up to the date, there are nine laboratories in integrated in GILABVIR and they are used in courses offering t o curricula of: Electrical Engineering, Telecommunications Engineering, Computing Engineering, Industrial Engineering and Civil Engineering. Technical and didactic aspects of them have been collected and classified. The two main goals of this group are to detect common needs of the technical solutions of the different laboratories and design new ed ucational methodologies that use virtual and remote laboratory based teaching activities.

The first goal is related to the implementation of a software application to join all the virtual and remote laboratories the UPC digital campus (Moodle platform) and all low student execute experiment and teachers propose monitor and evaluate these experiments, instead of spending a lot of time developing access and activity management applications. A dedicated software tool (Moodle Lab) is being programmed in order to control and monitor the access and execution of an experiment. With this option, professors can enable or disable the access to each experiment offered in each course and can also obtain information, individually for each student, about the timing, the con figuration parameters or the obtained results.

These data are used to evaluate the students. For most of the virtual and remote laboratory based learning activities, professors can obtain automatically a list of numerical results and records.

The second goal aims to prove the student’s learning outcomes, taking into account the design of the learning activities in the context of the European Higher Education Area, HEA, both in specific knowledge and particularly in specific skills.

Paper Outline—The rest of the paper is organized in five sections. After an introductory section I, section II is dedicated to define the virtual and remote laboratories and describe their characteristics, emphasizing the differences and comparative features between them. The virtual and remote GILABVIR laboratories are described in section III. Section IV presents an innovative teaching methodology based on these laboratories and related to a generic skill list. Finally, the conclusions are described in section V.

II. VIRTUAL AND REMOTE LABORATORIES

The goal of the environment is becoming more diversified and interdisciplinary in the type of activities offered to students. Virtual and remote laboratories have been developed by combining experimentation, homework and use of information and communication technologies. In this context, the problem is to execute an experiment at distance, two different methodologies must be distinguished: Virtual Laboratories and Remote Laboratories.

A Virtual Laboratory is defined as an interactive environment for designing and conducting simulation experiments. The experiment consists in running a program to a remote server machine. To start this program the user accesses the server through a user interface. A software monitoring platform starts the simulator program. The program models some real experiment behavior or produces output such as graphs, etc., and produces data that are set on input parameters to the user.

A Remote Laboratory is defined as an interactive environment designed to allow users to remotely control real laboratories. A monitoring platform is installed on a remote server machine. To start the experiment the user accesses the monitoring application through a web interface and configures an input parameter set. After the experiment, measured data or
Signals are obtained and returned to the user through the monitoring application.

As it can be deduced from the previous definitions, virtual laboratories and remote laboratories are extremely similar in the sequence of steps to follow when a practice is executed. Teaching methodologies base on these two kinds of laboratories are also very similar.

The GILABVIR group has been formed by faculty members who use virtual or remote laboratories in their teaching courses. Nine different projects directly related to nine different laboratories are currently grouped.

Virtual and remote laboratories that joined the GILABVIR initiative are described in the following list.

A. Remote and virtual laboratories for mechatronics and energetics students.

Different platforms have been designed to allow students to access the more suitable or virtual tools to complement the local laboratory sessions. These platforms are used in electrical engineering courses related to automation, mechatronics, motor control, renewable energy generation and power systems. Students program and supervise real systems as if they were working with real installations. This is done by using examples of standard PLC (Programming Logic Control) programming software provided by the PLC manufacturers.

Remote laboratories include: Automation and motor control laboratory, flexible manufacturing cell, Power Quality Laboratory, measurements of harmonic content in different loads, power system laboratory, protection, fault detection and restoration of electrical power systems.

Virtual laboratories in clude: DC motor control laboratory, Hotel automation laboratory, Chemical process automation.

B. LAVICAD

The virtual laboratory of analog and digital communication systems is a useful tool to verify the performance of different communication systems and digital signal processing techniques, topics typically integrated in an undergraduate course of telecommunications engineering. The communication systems have been implemented and designed as Java applications and are free available. They can be run at the e-learning platform: co - mweb.upc.edu. The different communication systems present different levels of user interaction and when students execute a system integrated in a common course, the obtained results can be supervised by the professor as an evaluation and assessment tool. From a pedagogical point of view, this laboratory has been created to facilitate the learning of certain matters, acting as a connection between the model of knowledge based on concepts and theories, and their practical understanding and experimentation.

C. Project: 62, an interactive tool to study discrete time signals and systems.

62 is an interactive tool written in JAVA that allows, first, to define discrete time signals and their stims, and then to work with them. Signal operations are specified by means of menus or dialog windows without the need of knowledge of any programming language. One of these menus is devoted to specifying digital filters (FIR and IIR) both in the frequency and in the time domain. The tool includes a graphic interface to show the sequences, their Fourier transform and the characterization of linear invariant systems (frequency response, impulse response). The tool uses the A/D and D/A converters of the PC sound card. Thereby, the tool can generate and filter an analog signal in real time. 62 is part of the experimental framework designed for the study of discrete time signals and systems to carry out their practical training. This tool is freely available in [4].

D. iLabRS: Remote laboratory for Secondary Education.

iLabRS is built over a Modular platform to perform remote experiments in sensors and signal conditioning. It uses two experiment boards, which together with additional boards...
allow doing currently 13 different practices. The remote Laboratory is aimed for secondary Education students, to allow them to perform online real experiments, with remote access through Internet. The aim is triple: giving a tool to increase the experimentality in scientific and technological subjects, demanding that the potential of the ICTs’s use and establishing a bridge between the secondary school and the university.

E. LEARN-SQL

LEARN-SQL is a system conforming to the IMS/QL specification that allows on-line learning and assessment of SQL students on SQL and data base skills in an automatic, interactive, informative, scalable and extensible manner.

This tool facilitates the definition of virtual laboratories or remote questionnaires that are used by students of subjets to learn design and use of relational databases in the UPC.

LEARN-SQL is a tool whose main goal is helping in learning the use and design of relational databases in different subjects of schools of the UPC. More specific goals are to:

- Provide the possibility to define virtual laboratories or remote questionnaires to be solved by the students at class or at home.
- Facilitate the participation of the students in its self-learning of database subjects.
- Provide students with valuable feedback, so that they can learn from their mistakes.
- Automatically evaluate the correctness of any SQL statement (queries, updates, stored procedures, triggers, ...) and the relational database abases relational algebra (Relational Algebra) with independence of the student solution.
- Help teachers define the questions or items in the remote questionnaires as well as allowing them to review the solutions provided by the students.
- Adapt the subjects where it is used to the European Higher Education Area (EH EA) and to innovative education methodologies.

F. Circuit and Communication Systems Simulators

This virtual laboratory is still in construction.

The aim is to develop monitoring tools for homework based on running software simulators or remote laboratory experiments. The monitoring tool will automatically send a report to a Moodle platform. It will be based on a Python module with functions to write ASCII text, formatted text, results tables and figures in the report to gether with the answer to questions asked to the student.

This project is to be implemented in the following activities of the UPC “European Master of Research on Information and Communication Technologies”:

Course: “Electron and electromagnetics”. Activity: Analysis of a transmission line with impedance discontinuities using many different numerical methods in frequency or time domains. The result is all the different methods are compared in terms of accuracy and computational efficiency.

Course: “Design and analysis of R F and Microwave Systems for Communication”. Activity: five remote control of a network analyzer using the high-frequency circuit simulator ADS.

G. Modular platform to perform remote experiments in sensors and signal conditioning [8].

It is based on a custom acquisition board which includes an Ethernet capable microprocessor, so that every board has its own IP address. The connection of multiple boards to a switch allows the access to multiple experiments and/or to multiple replica of an experiment. Every board gives power supply and control signals to specific experiment boards that are connected to the control board in a star-like structure. The sensors are A/D channels (16 bits), 2 D/A channels (14 bits), 8 control bits and a SPI bus. The experiment server runs specific applications made in LabView to control the experiments. Every application generates a remote panel that allows its use with a web browser. The link with the remote panel URL is placed among the course materials in the digital campus Atenaze. This platform gives a certain degree of security, the user authentication and a basic record of the user activity. Four different experiment boards have been developed up to now, which allow performing 6 different laboratory activities around the sensor characterization and the set-up of conditioning and acquisition circuits. The use of the remote laboratory is focused as a complementary tool to ad-hoc flexibility to the laboratory courses, mainly with the semi-distance students.

H. Virtual Lab: remote workstation for instrumentation and sensors [9].

Remote laboratory based on a web server and a VXI modular instrumentation system connected to a remote board with experiments and to a weather station. The access is made through a website (virtuallab.upc.es) using a password. It only admits a single simultaneous user, who can use the resources during 20 minutes. Seven different laboratory activities can be carried out, from a system identification and control, sensor calibration and remote control of instrumentation. In operation from 2003, the user interface was designed with the criterion of minimizing the changes and errors in the user interface. As a result of this, the control applications in LabView that control the experiments are running in the server and they just exchange parameters and results with the user through the web pages.

I. rWLAB-Remote WaveLab

The goal of this laboratory is to convert an experimental setup (wave channel) into a platform for teaching, research and dissemination of knowledge using all the advantages offered by today’s information technologies. Thus, we propose the creation of a knowledge portal based on remote experimentation with small-scale physical models with the field of Mariti me Engineering. The purpose of this portal will be to provide the container of those remote and virtual laboratories that can be
developed from the initiative. It is envisaged to provide the necessary content to the platform so that a rough simulation, experiment, or test could achieve the varying knowledge levels of methods and technologies employed in the experimental scale.

III. CONNECTING GILABVIR PROJECTS TO MOODLE.

One of the main technical aims of the GILABVIR group is the connection of all the projects to the UPC digital campus. The UPC digital campus is a Moodle platform and it is called Atenea. In [3] some guidelines are proposed in order to connect virtual and remote laboratories to an educational platform.

Moodle Lab is the application designed to connect all the distance lab oratories to the UPC digital campus. It is integrated by the connection module JLab and by the booking module.

A. Moodle Connection Module

The connection functionality allows the different laboratories to be run from a Moodle site. When a Moodle experiment is invoked through the Moodle platform there are some questions that are identified to be performed in order to communicate the virtual and remote laboratories with the Moodle database to store practice results and then allow teachers to view them.

The application that has been implemented is a new module for Moodle called JLab. JLab:

1. Centralize the management of the simulators that can be used in practices.
2. Allow laboratories to send the results to the server in order to be stored in the Moodle database.
3. Enable teachers to see the results of the practices from the portal and download them in Excel format.

The user enters in the main portal to access the module in any course. On the main page of the Moodle module operation process from the applet request to the results display, the communication protocol for a virtual Java-based laboratory, but the strategy is duplicated for virtual or remote laboratories, using Java or Adobeview as software monitoring platforms.

1. The user enters in the main portal using any browser. Then the user enters a JLab practice of any of his courses.
2. It shows the simulator applet using Javascript embedded in view.php.
3. View.php obtains the id of the user connected, the id of the practice selected and a parameter that indicates if it is necessary to send the results to the server.
4. Applet is loaded.
5. Each stage of the applet, upon completion, generates an XML file with the results.

6. This XML is sent to the server, the c ombeans.php file parses data and inserts them in the table mdl_jlab_results.
7. JLab also implements the report.php file which will show all users results of each practice.

Figure 2 shows the system architecture for distance laboratories.

![JLab - System Architecture](image)

JLab module has been currently finalized and is being tested with a virtual laboratory (II.B) and with a remote laboratory (II.D). It is expected to connect all GILABVIR laboratories to Atenea campus on June 2019.

B. Moodle Booking Module

If the experiment is performed in a remote laboratory and the number of local workplaces is limited, a booking planning strategy becomes necessary. A dedicated Moodle module is being designed to allow booking functionality and JLab module coordinates work. The booking strategy defined for our laboratories integrates:

- Students and teachers can book a workplace session some days in advance.
- A booked session can be modified or canceled.
- The occupancy time per session is confirmed by a laboratory administrator.
- The dedicated Moodle application assists the workplace to the booked sessions.
- A workplace inactivity detector releases the inactive workplaces and these are automatically available for other booked sessions.
- Teachers can supervise if a booked session is occupied by its owner.
- Laboratory responisibles and teachers can periodically check the statistical books and the statistical use of the workplaces in the laboratory.

The Moodle booking module is currently being tested with a remote laboratory (II.D).
IV. ACADEMIC USE OF VIRTUAL AND REMOTE LABORATORIES

One of the main goals of the Interest Group is to share and improve the academic activities related to the use of virtual and remote laboratories. Two different aspects of this process have been identified: the interaction strategies (how to use the virtual and remote labs within our subjects) and the learning methodology (what to do, evaluation, incidence in specific and generic skills, ...).

After a survey within the group members, we can conclude that the virtual and remote labs are used both in classroom and remote activities. In addition to its remote use by the students, almost all labs are also used as demonstrators in classroom to support the teaching explanation and as servers in laboratory sessions to enhance the in-situ activities. While some of the laboratories is used as an additional and independent activity and another as a substitute of current laboratory activities, all others are used as complementary activities. Concerning the assessment, one half of the subjects including virtual or remote laboratories use them as voluntary issues while the other half specifies a given percentage of the mark. To perform the assessment, two of the involved subjects perform an automatic harvesting of results, a third one performs an automatic evaluation of the homework and the remaining one or two performed an automatic offline gathering of reports.

Concerning the learning outcomes, the virtual and remote laboratories should help to improve the specific skills. The mandatory skills defined by our University, the survey shows that the use of virtual or remote laboratories can contribute to acquire the following skills: self-learning (8), effective use of learning resources (4), team work (3), innovation and entrepreneurship (1) and use of foreign language (1). Additionally, the different teaching methods can refine the learning skills like: “experimental behavior or and instrumentation knowledge” or “engineering problems identification, modeling, formulation and solving”. Most of them are also identified as targets of virtual and remote labs.

Several virtual and remote laboratories have been built with a higher stress in their technical aspects than in their didactical aspects. An outcome of the Interest Group activity has been the recommendation of plans aning the virtual and remote laboratories as standard academic. That is, with a lifecycle that starts at the subject goals, defines a given learning activity, includes a deliverable that can be assessed and closes the cycle with an evaluation of the laboratory performance based on indicators. The learning activity should incorporate a form which, in addition to the technical content of the activity, gives information of all the hat aspect s to the students. This includes the objectives and assessment criteria of the generic skills to be handled. As an example, the table II describes the goals at three depth levels of the generic skill “engineering problems identification, modeling, formulation and solving”. Each row in the table represents a different virtual or remote laboratory based activity that can be proposed to acquire the skill. Levels 1 and 2 are suitable for first and second years of an engineering degree and level 3 is proposed for third and fourth years. Goals at level 3 usually also serve to acquire more generic skills, as for instance “C cooperative Learning” and “Autonomous Learning”.

V. CONCLUSIONS

The main aim of the GILAB VIR group can be divided in two lines. As a result of detecting common needs of the technical solutions of the different laboratories, first line is related to the implementation of a software application to join all the virtual and remote laboratories. The UPC digital campus Atenea m oodle pl atform and all lowest udent s execute experiments and teachers propose monitor and evaluate these experiments. The second main line is related to the design of new educational methodologies that use virtual and remote laboratories based teaching activities to improve the students learning outcomes but in specific knowledge and generic skills.

Concerning the learning effectiveness of virtual and remote laboratories, among the students presented in [10] at study is presented where their authors conclude that learning performance using dynamic media is significantly higher than those of the static textbook lesson, especially if the dynamic media can support or learning when cognitive load and learning er s mental representations. Furthermore, based on our experience, we can assure that the learning effectivenes of dynamic resources doesn't depend on if they are offered by internet or in a laboratory classroom, but it is highly correlated with the teacher ability to choose the appropriate experiments to be made to work each subject or sequence of subjects in the program.

ACKNOWLEDGMENT

The authors wish to acknowledge all GILAB VIR members for their aid and support provided throughout each activity and meeting, the enrolled students who have implemented most of platforms and applications and the RIMA management team for their institutional support.
