ABSTRACT

We deposited BiFeO₃ films on stainless steel substrates using a simple low-temperature wet-chemical route. We used bismuth and iron nitrates as metal source and two chelating agents, citric acid and polyvinyl alcohol, in water to prepare a solution and deposited the film by dipping the steel substrate in the viscous solution.

We have investigated the structure of the BiFeO₃ film on steel by HRSEM, TEM, HRTEM, EDS and EELS. The film deposited on the steel substrate has two sublayers: a very thin (about 100 nm) nanocrystalline layer, with crystallite size of few nms, and a thicker (about 1 micron) crystalline layer.
