Active Microwave Imaging of Inhomogeneous Bodies

CHRISTIAN PICHOT, LUIS JOFRE, GUILLAUME PERONNET, AND JEAN-CHARLES BOLOMEY

Abstract—A numerical method and experimental technique for microwave imaging of inhomogeneous bodies is presented. This method is based on the interpretation of the diffraction phenomena and leads to tomographic reconstruction of the body under investigation. Various numerical examples are given on spatial impulse response, recognition of dielectric rods, inhomogeneous bodies, and simulated human arm. Different experimental results on dielectric rods and isolated animal organs are also given.

I. INTRODUCTION

URING THE LAST few years, it has been possible to observe a fantastic development of tomographic processes for biomedical purposes. X-rays, ultrasonic waves and, more recently, nuclear magnetic resonance are the most popular examples.

Oddly, active imaging systems based on microwaves are in the beginning stage [1]-[7], [9], [11]-[13], [15]-[17], [28], [29]. However, there are some reasons for that. A priori ideas are the difficult penetration of microwaves in living tissues, their high attenuation constant, and their poor resolution.

In fact, the first experiments of Larsen and Jacobi [1]-[3] revealed that these drawbacks can be overcome and that microwave imaging had some potentialities, mainly resulting from the specificity of the interaction mechanisms with the living tissues, different from those encountered with X-rays or ultrasonic waves for instance.

The problem of field penetration into high water content tissues can be solved by a careful matching of the applicators; the attenuation rate is compatible with the present state-of-the-art in the receiver sensitivity area for thicknesses as large as a few centimeters. Finally, the resolution is better than could be imagined because of the high permittivity constant of tissues with large water content. For example, the wavelength in such tissues is about one centimeter at an operating frequency equal to 3 GHz.

Thus, the expected resolution, on the Rayleigh criterion basis, is of the order of 6 mm, i.e., about half a wavelength at 3 GHz in water. This has been confirmed both on numerical simulations and experimental results. If X-rays CAT scanners have better resolution (fraction of mm), the information available in a microwave image is potentially quite different.

The experimental processes depend on the reconstruction algorithm to be used. The first method, strongly related to X-ray tomodensitometry, is based on a linear path assumption between an emitter and a receiver. Measuring the transmission coefficient during the simultaneous displacement of the antennas provides one projection. From many projections corresponding to different orientations, it is possible to deduce cross sections of the volume under test. The second method belongs to holographic techniques. For a given irradiation of this volume, the scattered field is recorded on a finite surface (hologram) and the image of the domain under investigation is numerically obtained by simulating the effect of an optical focusing system. Such an approach is based on a better description of the microwave-tissues interaction. However, comparisons are not yet available to enable conclusions with respect to the advantages of each method.

This paper is devoted to the description of efficient algorithms for the diffraction tomography. By efficient, one means that the required computations can be done in quasireal time in realistic situations. These situations resulted from experiments conducted on phantoms or perfused organs, and from "exact" numerical simulations. These experiments used a fast microwave camera, which has been described elsewhere [13], [15], providing a recording duration of the order of the reconstruction time. Besides, numerical simulation was found to be very useful for fine estimation of contrasts and complementary to the experimental approach.

In this paper, first the tomographic algorithm is presented for two-dimensional inhomogeneities. Second numerical results obtained from simulation are given in order to evaluate the spatial impulse response, the resolution, and the accessible contrast. Then the reconstruction of inhomogeneous and complex bodies is considered.

The third section is devoted to the description of the experimental setup and to the discussion of the result obtained on dielectric rods and isolated organ (perfused and nonperfused horse kidney).

II. TWO-DIMENSIONAL THEORY

One considers a cylindrical object of arbitrary cross section $S$ which is characterized by a dielectric permittivity $\varepsilon_S(x, y)$ and a conductivity $\sigma_S(x, y)$. This object is illuminated by a plane wave for which the electric field $\mathbf{E}^0$ is parallel to the cylinder axis $(z$ axis) as depicted in Fig. 1(a).

The external medium is assumed to be uniform and characterized by a dielectric permittivity $\varepsilon$ and conductivity $\sigma$. The permeability is that of vacuum $\mu = \mu_0$ in each medium. Let $\mathbf{E}$ represents the total electric field and $\mathbf{E}^d$ the diffracted field which is generated by the equivalent electric current radiating in the external medium so that

$$\mathbf{E} = \mathbf{E}^i + \mathbf{E}^d$$

(1)

where the equivalent electric currents are defined as usually

$$\mathbf{J}_e(x, y) = (k_s^2(x, y) - k^2)\mathbf{E}(x, y)$$

(2)

with

$$k_s(x, y) = \sqrt{\omega^2 \mu_0 \varepsilon_S(x, y) - k^2}$$

$$k_0(x, y) = \sqrt{\omega^2 \mu_0 \varepsilon(x, y) - k^2}$$

1 Taking into account the limitation of the incident power density for a total harmlessness under the safety standard (<10 mW/cm$^2$).
The total field \( E \) can be exactly calculated with an integral for any point \((x, y)\) inside or outside the object. The Green’s function \( G(x, y, x', y') \) is given as (Tyras [23] for the integral representation)

\[
G(-x,Y;X',Y') = \frac{-i}{4} \int_0^1 \frac{e^{-i\sqrt{k^2 - 4\pi^2 v^2}|y - y'|}}{\sqrt{k^2 - 4\pi^2 v^2}} \ e^{-i2\pi v(x-x')} \ dv
\]

with

\[ \text{Im}(\sqrt{k^2 - 4\pi^2 v^2}) \leq 0. \]

One notes that the \( \vec{E}_i, \vec{E}_d \), and \( \vec{E}_d \) vectors have only \( z \) component.

The solution of the direct problem (computation of the total or diffracted field from the knowledge of the geometrical and electromagnetic characteristics of the object with a given incident field) can be carried out with the moment method (Richmond [19], Iskander et al. [24], [25]) or in some cases with an iterative technique in connection with the Born approximation (Barthes and Vasseur [22]). For the inverse problem which consists of finding the shape and electromagnetic characteristics \( \epsilon_0(x, y) \) and \( \sigma_0(x, y) \) of the object for a given incident field, when the diffracted field is measured along a segment line, equivalent methods can be applied (Barthes and Vasseur [22], Ghodgaonkar et al. [26]). However, powerful computers are needed when the cross-section dimensions of the bodies are of the order of one wavelength or more.

The following method for the inverse problem can readily be used on a microcomputer or array processor.

Consider the case where a plane wave is incident at an angle \( \theta \) with respect to \( y \) axis and where the probing line for diffracted field data is perpendicular to the incident propagation vector \( \vec{k} \) (see Fig. 1(b)). Let \( \psi(\theta; x, y) \) represent the normalized diffracted field as

\[
\psi(\theta; x, y) = \frac{E_d^d(\theta; x, y)}{E_i^i(\theta; x, y)}
\]

where \( E_d^d(\theta; x, y) \) is the diffracted field related to the incident field \( E_i^i(\theta; x, y) \). Introducing \( \psi(\theta; x, y) \) in (4) leads to

\[
\psi(\theta; x, y) = [E_i^i(\theta; x, y)] \int_S E_d^d(\theta; x', y')K(\theta; x', y') 
\cdot G(x, y; x', y') \ dx' \ dy'
\]

with

\[ K(\theta; x, y) = (k_i^2(x, y) - k^2)(1 + \psi(\theta; x, y)) \]

is the normalized electric current. Let us define the new frame \((X, Y)\) as

\[ X = x \cos \theta + y \sin \theta \quad x = X \cos \theta - Y \sin \theta \]
\[ Y = -x \sin \theta + y \cos \theta \quad y = X \sin \theta + Y \cos \theta. \]

Equation (7) becomes

\[ \Psi(\theta; X, Y) = e^{ikr} e^{-ikr} \int_S E_d^d(\theta; X', Y')K(\theta; X', \cos \theta) 
\cdot G(X, Y; X', Y') \ dX' \ dY' \]

with \( \Psi(\theta; X, Y) \) normalized diffracted field in the new frame. The use of the integral representation (5) of \( G(X, Y; X', Y') \) yields

\[ \Psi(\theta; X, Y) = \frac{-i}{2} \int_{-\infty}^{\infty} e^{-ikr} \left( \psi(\theta; X', \cos \theta) 
\cdot e^{-ikr} \frac{1}{\sqrt{k^2 - 4\pi^2 v^2}} \right) 
\cdot e^{-i2\pi v(x-x')} \ dv \]

Let \( \hat{\Psi}(\theta; \nu, Y) \) be the Fourier transform of \( \Psi(\theta, X, Y) \) with re-
spect to \( X \)

\[
\hat{\psi}(\theta; \nu, Y) = \int_{-\infty}^{\infty} \hat{\psi}(\theta; X, Y) e^{2\pi i X} dX
\]  

(11)

then from (10) we obtain

\[
\hat{\psi}(\theta; \nu, Y) = \frac{1}{2} e^{ikY} \int_{S(X', Y')} e^{-i \sqrt{k^2 - 4\pi^2 \nu^2} Y} K(\theta; X' \cos \theta
\]

\[
- Y' \sin \theta, X' \sin \theta + Y' \cos \theta) \frac{e^{-i \sqrt{k^2 - 4\pi^2 \nu^2} |Y - Y'|}}{\sqrt{k^2 - 4\pi^2 \nu^2}}
\]

\[
\cdot e^{2\pi i X'} dX' dY'.
\]  

(12)

For any \( Y_0 > \max \{ Y' \in S(X', Y') \} \) in the frame \((X', Y')\), (12) becomes

\[
\hat{\psi}(\theta; \nu, Y_0) = \frac{1}{2} e^{ikY_0} \int_{S(X', Y')} \frac{e^{-i \sqrt{k^2 - 4\pi^2 \nu^2} Y_0}}{\sqrt{k^2 - 4\pi^2 \nu^2}} K(\theta; X' \cos \theta
\]

\[
- Y' \sin \theta, X' \sin \theta + Y' \cos \theta) \frac{e^{-i \sqrt{k^2 - 4\pi^2 \nu^2} |Y - Y'|}}{\sqrt{k^2 - 4\pi^2 \nu^2}}
\]

\[
\cdot e^{2\pi i X'} dX' dY'.
\]  

(13)

where

\[
\int_{S(X', Y')} K(\theta; X' \cos \theta - Y' \sin \theta, X' \sin \theta + Y' \cos \theta)
\]

\[
\cdot e^{2\pi i (-k/2 + 1/2 \pi \sqrt{k^2 - 4\pi^2 \nu^2}) Y'} e^{2\pi i X'} dX' dY'
\]

\[
= \int_{S(X', Y')} K(\theta; x', y') e^{2\pi i (\mu(\nu) \cos \theta + \nu \sin \theta)}
\]

\[
\cdot e^{2\pi i (-\mu(\nu) \sin \theta + \nu \cos \theta)} x' dX' dy'
\]  

(14)

with

\[
\mu(\nu) = \frac{k}{2\pi} + \frac{1}{2\pi \sqrt{k^2 - 4\pi^2 \nu^2}}.
\]  

(15)

Let \( \hat{K}(\theta; \nu, \mu) \) be the two-dimensional Fourier transform of \( K(\theta; x, y) \)

\[
\hat{K}(\theta; \nu, \mu) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} K(\theta; x, y) e^{2\pi i (\nu x + \mu y)} dx dy.
\]  

(16)

The relation (14) defines a usual two-dimensional Fourier transform of \( K(\theta; x, y) \) (its support is bounded to \( S(x, y) \) so the integrals can be extended to infinity) on a curve \((\alpha(\theta; \nu), \beta(\theta; \nu))\) only if we restrict \( \mu(\nu) \) to \( \Omega(\nu) = \Re(\mu(\nu)) \).

In this case and from (13) we deduce a direct relation between \( \hat{K}(\theta; \alpha(\theta; \nu), \beta(\theta; \nu)) \) and \( \hat{\psi}(\theta; \nu, Y_0) \):

\[
\hat{K}(\theta; \alpha(\theta; \nu), \beta(\theta; \nu)) = 2i\sqrt{k^2 - 4\pi^2 \nu^2} e^{2\pi i \Omega(\nu) Y_0} \hat{\psi}(\theta; \nu, Y_0)
\]  

(17)

with

\[
\alpha(\theta; \nu) = \nu \cos \theta - \Omega(\nu) \sin \theta
\]  

(18)

\[
\beta(\theta; \nu) = \nu \sin \theta + \Omega(\nu) \cos \theta
\]  

(19)

A choice on \( k \) and \( \nu \) yielding \( \Omega(\nu) \) is to take \( k' = \Re(k) \) (instead of \( k \)) and \( \nu < k'/2\pi \). This choice leads to reconstruct in a lossless outer medium (of wavenumber \( k' \)) and neglect the spatial frequency \( \nu \) for \( \nu > k'/2\pi \). In order to combine every rotation information, let \( \mathcal{P}(\theta; \alpha, \beta) \) be the function defined in the spectrum domain as

\[
\mathcal{P}(\theta; \alpha, \beta) = \begin{cases} 
1 & \text{if } (\nu, \mu) \in (\alpha(\theta; \nu), \beta(\theta; \nu)) \\
0 & \text{elsewhere}.
\end{cases}
\]  

(20)

For \( N \) rotations \( \theta_n (n = 1, \ldots, N) \) with \( \theta_\pi = 2\pi N(n = 1) \) and using the information obtained from each one, one reconstructs

\[
\mathcal{K}(\alpha, \beta) = \sum_{i=1}^{N} \mathcal{P}(\theta_i; \alpha, \beta) \hat{K}(\theta_i; \alpha, \beta)
\]  

(21)

in the \( D \) spectrum domain (\( \alpha, \beta \in [-k', k'] \)) (See Fig. 2 for \( N = 4 \)). One has a set of semicircles passing through the central point \((0, 0)\). The function \( \mathcal{K}(\alpha, \beta) \) is the Fourier transform of the image \( \mathcal{K}(x, y) \):

\[
\mathcal{K}(x, y) = \sum_{i=1}^{N} [(k_i^2(x, y) - k^2)(1 + \psi(\theta_i; x, y))] \ast P(\theta_i; x, y)
\]  

(22)

and the asterisk means the convolution product.

The main problem when combining the different \( \hat{P}(\theta_i; \alpha, \beta) \) is the multiple values of \( \hat{K}(\theta_i; \alpha, \beta) \) at a same point. The adopted method is to take the average value.

Note that in the Born approximation (\( \psi(\theta_i; x, y) \ll 1 \)), the reconstructed image is

\[
\mathcal{K}(x, y) = (k_i^2(x, y) - k^2) * \mathcal{P}(x, y)
\]  

(23)

where \( \mathcal{P}(x, y) = \Sigma_{i=1}^{N} P(\theta_i; x, y) \) is the spatial impulse response of the system.

An important aspect of the reconstruction method is the numerical estimate of the \( \mathcal{K} \) normalized equivalent current \( \mathcal{K}(x, y) \) from the knowledge of \( K(\alpha, \beta) \) with a limited number of rota-
tions [27]. This computation being based on a discrete Fourier transform (fast Fourier transform for example). The values of \( \hat{K}(\alpha, \beta) \) are required on a uniform discrete lattice. This implies a problem of interpolation or weighting.

Practically the diffracted field is measured on a segment line. Thus, to take into account the length \( a \) of the segment line, we define \( \hat{\Psi}_d(\theta; \nu, Y_0) \) the measure at \( Y = Y_0 \) as

\[
\hat{\Psi}_d(\theta; \nu, Y_0) = \int_{-a/2}^{a/2} \Psi(\theta; X, Y_0) e^{i2\pi X} dX
\]

where

\[
\hat{\Psi}_d(\nu) = \frac{\sin(\pi \nu a)}{\pi \nu}
\]

### III. NUMERICAL RESULTS

The spatial impulse response, the resolution, the contrast, the reconstruction of dielectric rods and complex bodies are now investigated.

The computation of the normalized diffracted field \( \Psi(\theta; X, Y_0) \) from (4) is obtained by means of the moment method, which leads to a system of linear equations [19], [24], [25]. The size of this system is function of the number of cells in the object (the rods in this case) where the electric field is supposed to be constant. In most cases the size of the cells does not exceed \( 0.2 \lambda_{\omega}/\sqrt{\varepsilon_r S} \).

#### A. Spatial Impulse Response

The use of reconstruction procedure implies to know the influence of:
- spectrum limitation between \(-k'\) and \(k' (k = k' - ik'')\);
- reconstruction in a lossless outer medium;
- sampling interval of the measured field and probing line length;
- number of views, (or rotations).

The spatial impulse response can give a qualitative and quantitative characterization of the image. With this goal, we suppose that \( K(x, y) = \delta(x - x_p, y - y_p) \) where \( \delta(x - x_p, y - y_p) \) is the Dirac distribution at \((x_p, y_p)\) point and we try to recover it using one view.

One the one hand let \( \delta_x \) by the transversal spatial impulse response along \( x \)-axis.

On the other hand, let \( \delta_y \) be the longitudinal spatial impulse response along \( y \)-axis.

As an example, Fig. 3 shows the values of \( \delta_x \) and \( \delta_y \) for a Dirac distribution \( \delta(x, y) \) located at \( x_p = 0 \) and \( y_p = -1.16 \) cm in a lossy medium (water: \( \varepsilon_r = 74, \sigma = 2.39 \) S/m) at 3.0 GHz (the wavelength in this medium is \( \lambda = \lambda_{\omega}/\sqrt{\varepsilon_r S} = 1.16 \) cm).

We first discuss the influence of the length \( a \) of the probing line. From the elementary source \( \delta(x, y) \) located in \( P \), the probing line is seen with a half-aperture angle \( \theta_0 \).

In Fig. 4 are represented the results on \( \delta_x \) and \( \delta_y \) for different aperture angles \( \theta_0 \) (30°, 45°, 60°, and 90°) in water medium at 3.0 GHz. The point source is located at \( x_p = 0 \) and \( y_p = -3.5 \) cm = \(-3 \lambda \) and the measurement line is situated at \( y_p = 0 \).

The sampling interval \( \Delta x \) of the measured field is given by virtue of Shannon theorem under the assumption that the spectrum
is zero for \( |\alpha| > |k'| \):
\[
\Delta x = \frac{\pi}{k'} = \frac{\lambda}{2}
\]
(\( \lambda \) is the real part of the wavelength in the outer medium).

Concerning the spectrum truncature, the Fourier transform of the diffracted field is very attenuated for \( \nu > k'/2\pi \) at for a distance \( y_0 > \lambda/2\pi \).

So no significant information (in this medium) can be recovered for \( y_0 > \lambda/2 \), the spectrum being too much attenuated. However for \( y_0 < \lambda/2 \), the sampling interval can be taken < \( \lambda/2 \) to take into account the evanescent waves.

Object rotation can improve significantly the spatial impulse response.

B. Identical Rods

The reconstruction of two lossless dielectric square rods surrounded by water is investigated at 3 GHz frequency. The two rods are illuminated by a plane wave and their centers are separated by a distance of 2.8 cm as shown in Fig. 5.

The characteristics of the rods are \( \varepsilon_r = 2.4 \) and \( \sigma = 0 \) S/m, the ones of water have been given above; the probing line length is 14 cm.

The distance between the probing line and the rods is \( y_0 \) and the sampling interval on the probing line is \( \Delta x = 0.58 \) cm. With four rotations of the rods around their symmetry point (four views), we obtain the amplitude of \( \hat{K}(x, y) \) shown in Fig. 5.

C. Rods with Different Electromagetical Characteristics

We investigate now the situation of two rods with different permittivities and conductivities (respectively, \( \varepsilon_{r1}, \sigma_1 \) and \( \varepsilon_{r2}, \sigma_2 \)) to determine the minimum contrast between the two rods and with the surrounding medium. As above the distance between their centers is 2.8 cm, the sampling interval on the probing line (length 14 cm) is \( \lambda/2 \).

In Fig. 6(a) is shown the cross section in x direction at \( y = 0 \) of the amplitude \( |\hat{K}(x, y)| \) with one view (without rotation) for two lossless rods (\( \varepsilon_{r1} = 2.4 \) and \( \varepsilon_{r2} = 12 \)).

**Fig. 5.** Two identical rods (\( \varepsilon_r = 2.4 \) and \( \sigma = 0.0 \) S/m) separated by a distance of 2.8 cm. The outer medium is water \( \varepsilon_r = 74 \) and \( \sigma = 2.39 \) S/m. Amplitude \( |\hat{K}(x, y)| \) of the reconstructed image.

**Fig. 6.** (a) Modulus of \( \hat{K}(x, y) \) reconstruction (normalized with respect to the first rod) along the x axis for two different dielectric rods (\( \varepsilon_r = 2.4, \sigma = 0.0 \) S/m and \( \varepsilon_r = 12, \sigma = 0.0 \) S/m) separated by a distance of 2.8 cm and surrounded by water (\( \varepsilon_r = 74, \sigma = 2.39 \) S/m). (b) Modulus of \( \hat{K}(x, y) \) reconstruction (normalized with respect to the first rod) along x axis (\( y = 0 \)) for two lossy rods (\( \varepsilon_r = 80.0, \sigma = 2.39 \) S/m and \( \varepsilon_r = 74.0, \sigma = 1.0 \) S/m in water (\( \varepsilon_r = 74, \sigma = 2.39 \) S/m).

The difference level is about 3 percent for the modulus of \( K(x, y) \). The reconstruction of two lossy rods filled with a medium close to the surrounding water medium is depicted in Fig. 6(b). The characteristics of the two rods are, respectively, \( \varepsilon_r = 80, \sigma = 2.39 \) S/m and \( \varepsilon_r = 74, \sigma = 1.0 \) S/m (for the water medium \( \varepsilon_r = 74 \) and \( \sigma = 2.39 \) S/m). The difference level is about 40 percent between the two rods for the amplitude \( |\hat{K}(x, y)| \) at \( y = 0 \).

**IV. INHOMOGENEOUS OBJECTS**

A. Objects Composed of Fat, Muscle, and Bone

A square object (side \( a = 8 \) cm) with three dielectric layers simulating three kinds of human tissues (fat, muscle, and bone) surrounded by water illuminated by a plane wave at 3 GHz (Fig. 7) has been analyzed. The thickness of the fat medium is 1 cm, and the dimensions of the bone are 2 cm over 2 cm. The electromagnetic characteristics are, respectively, for fat, muscle, and bone, \( \varepsilon_r = 5 \) and \( \sigma = 0.2 \) S/m, \( \varepsilon_r = 46 \) and \( \sigma = 2 \) S/m, \( \varepsilon_r = 8 \) and \( \sigma = 0.22 \) S/m.

The probing line is located at 4.5 cm from the border of the
Fig. 7. Square object composed with fat, muscle, and bone surrounded by water. Reconstruction (modulus of $K(x, y)$) displayed on a TV monitor.

Fig. 8. Section of simulated human arm (upper segment) surrounded by water. Reconstruction (modulus of $K(x, y)$).
object and its length is 32 cm. The sampling interval is \( \lambda/2 = 0.58 \) cm. The object rotates in order to obtain four orthogonal views. From these views, the reconstruction of the normalized electrical current density \( K(x, y) \) is achieved. The amplitude \( |K(x, y)| \) is displayed on a TV monitor set (Fig. 7). Note that the object outline is relatively well described even if the number of views is very limited.

**B. Human Arm Simulation**

The reconstruction of a segment of a human arm (upper segment) from synthetically data is investigated (Fig. 8). The maximum length and width are, respectively, 8 cm and 6 cm and the average fat thickness is 0.5 cm. For the direct problem (computation of the diffracted field outside or inside the object and in particular on the probing line), we use the moment method applied to (4). The length of the simulated probing line is 32 cm and it is separated from object by a distance of 2.25 cm (Fig. 8). The sampling interval on the data acquisition line is \( \Delta x = 0.58 \) cm. The normalized current distribution \( K(x, y) \) is reconstructed using four orthogonal views and the modulus \( |K(x, y)| \) is displayed on a TV monitor screen. The fat thickness and bone presence are clearly visible.

**V. EXPERIMENTAL RESULTS**

Various configurations have been investigated in order to obtain a quasireal time measurement [13], [14], [15]. The method requires the knowledge of the normalized diffracted field on a segment line; and instead of moving a probe, which is time-consuming, the modulated scattering technique (MST) [13], [15], [20] provides the speed of probe array without the need of microwave multiplexing. This technique allows a very short acquisition time: about 1 ms per point.

Fig. 9 shows the experimental setup operating in transmission.

The emitting source is an applicator constituted by a nonuniform guiding structure [21] which generates an incident field with a slowly varying amplitude and phase over a width \( L \) (the maximum attenuation of 3 dB maximum is given for \( L = 16 \) cm). The applicator is fed by a power generator so that the radiating power density is less than 10 mW/cm² (safety standard); it is matched to water with a dielectric slab \( (\varepsilon_r = 9) \).

The receiving system is constituted of an identical applicator in the aperture of which a linear array of 64 diodes-loaded dipoles is located. The interval between each dipole is \( \Delta x = 0.58 \) cm. The normalized current distribution \( K(x, y) \) is reconstructed using four orthogonal views and the modulus \( |K(x, y)| \) is displayed on a TV monitor screen. The fat thickness and bone presence are clearly visible.

Fig. 10. Experimental setup for resolution estimation with two dielectric rods \( (\varepsilon_1 = \varepsilon_2 = 2.4) \). Representation of \( |K(x, y)| \).

Fig. 11. Arrangement for three-dimensional object imaging (the object is translated along z axis).
Fig. 12. (a) Vertical slice image of a nonperfused horse kidney. (b) Vertical slice image of a perfused horse kidney. The perfusion tube is at the top of the organ.

Fig. 13. (a) Vertical slice image of a perfused pony kidney. (The temperature perfusion is 38°C.) (b) Vertical slice image of a perfused pony kidney. (The temperature perfusion is 41°C).
reconstructed from four orthogonal views, is shown in Fig. 10. This method has been applied to perfused and nonperfused organs to investigate on the one hand the degree of water and on the other hand the influence of perfusion temperature on the organ.

As shown in Fig. 11, the object is translated on the z axis in order to simulate a two-dimensional recording measurement with the probing line. Although the reconstruction method is based on cylindrical symmetry, it has been applied to three-dimensional object as an animal organ.

At each position of the probing line, we compute a horizontal tomo graphic image (horizontal slice as shown in Fig. 11). Various positions of the object along z axis allow the computation of a vertical tomo graphic slice (Fig. 11). A right horse kidney whose dimensions are approximately 12 cm X 15 cm X 20 cm is immersed in warm water (37°C).

Figs. 12(a) and 12(b) show the vertical image of a nonperfused and perfused horse kidney. In both images, outlines are well described (the image is displayed on a TV monitor with 16 color levels). The differences observed between the nonperfused and perfused cases illustrate the sensitivity of microwave imaging to the water content in biological tissues.

Other experiments have been made on a pony kidney to evaluate the influence of perfusion temperature. Figs. 12(a) and 12(b) show the conductivity changes due to a rise in temperature. As before, the organ is immersed in 37°C water and the perfusion temperature varies from 38°C (Fig. 13(a)) to 41°C (Fig. 13(b)). The temperature modifications can be visible with a resolution of 1°C approximately.

VI. CONCLUSION

In this paper we present a numerical method and experimental technique for active microwave imaging of inhomogeneous bodies which allow tomo graphic reconstruction of the normalized electric current for biomedical applications or target recognition. The method is based on the use of diffraction phenomena inside and outside the body using the diffracted field. By the use of performant algorithms as FFT, the tomo graphic reconstruction is carried out with low computing time (a few minutes on a mini computer HP 1000, a few seconds on an array processor).

Various examples are given from numerical simulations on homogeneous (dielectric rods) or inhomogeneous bodies (object with fat, muscle, bone), and from experimental results (dielectric rod, isolated animal organ) with illumination power compatible with the severe safety standards (atraumatic process).

The multiple illuminations (or rotations of the object) provide a spatial resolution of λ/2 where λ is the wavelength in the external medium (for a frequency of 3 GHz and water as external medium, λ = 1.16 cm).

Other applications as target analysis in air can be intended with this technique.

APPENDIX

THREE-DIMENSIONAL CASE

Consider a three-dimensional organ of volume V illuminated by a plane wave linearly polarized along the z axis. The diffracted field inside and outside the organ can be obtained from the following integral representation:

\[ \mathcal{E}_d(\mathbf{r}) = \frac{1}{k^2} \left( \overline{\nabla}^2 + k^2 \right) \int_V \mathcal{J}(\mathbf{r}') G(\mathbf{r}, \mathbf{r}') d^3r \]  

(25)

with

\[ \mathcal{J}(\mathbf{r}) = (k^2 \nabla^2 - k^2) \hat{E}(\mathbf{r}) \]  

(26)

\[ G(\mathbf{r}, \mathbf{r}') = \frac{e^{-ik|\mathbf{r} - \mathbf{r}'|}}{4\pi|\mathbf{r} - \mathbf{r}'|} \]

\[ = \frac{i}{2} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{e^{-i2\pi v_1(x-x')} e^{-i2\pi v_2(y-y')}}{\nu_2} \nu_2 \left( e^{-i2\pi v_3(z-z')} dv_1 dv_3 \right) \]

(27)

\[ \hat{E}(\mathbf{r}) = \hat{E}(\mathbf{r}) + \hat{E}(\mathbf{r}) \]

(28)

Assume the depolarization is negligible; thus \( \hat{E}_d \) is approximated by

\[ \hat{E}_d(\mathbf{r}) = \mathcal{E}_d(\mathbf{r}) \int_V \mathcal{J}(\mathbf{r}') G(\mathbf{r}, \mathbf{r}') d^3r \]

(29)

with \( \hat{E}_d \) as \( \hat{E}_d \) parallel to z axis. The plane wave is incident at an angle \( \theta \) in the \( x-z \) plane with respect to \( y \)-axis. Thus we can define \( \Psi(\theta; \mathbf{r}) \) as

\[ \Psi(\theta; \mathbf{r}) = \hat{E}_d(\theta; \mathbf{r}) \hat{E}_d(\theta; \mathbf{r}) \]

(30)

\( \Psi(\theta; \mathbf{r}) \) satisfies the following equation according to (29).

\[ \Psi(\theta; \mathbf{r}) = \left[ E_{\mathbf{r}}^d(\theta; \mathbf{r}) \right]^{-1} \int_V \mathcal{J}(\mathbf{r}') G(\mathbf{r}, \mathbf{r}') d^3r \]

(31)

with

\[ K(\theta; \mathbf{r}) = (k^2 \nabla^2 - k^2)(1 + \Psi(\theta; \mathbf{r})). \]

(32)

From (31) which is the three-dimensional extension of (4) and following the same steps as the two-dimensional case, one obtains the relation between the three-dimensional Fourier transform \( \hat{K}(\theta, \mathbf{r})(\mathbf{r} = (v_1, v_2, v_3)) \) of \( \hat{K}(\theta; \mathbf{r}) \) and the Fourier transform \( \Psi(\theta; v_1, Y_0, v_3) \) of the data acquisition \( \Psi(\theta; X, Y_0, Z) \) on a recording plane at \( Y = Y_0 \) position.

\[ \hat{K}(\theta; \mathbf{r}) = \alpha(\theta; v_1, v_3) \beta(\theta; v_1, v_3) \]

(33)

\[ = 2i(\sqrt{k^2 - 4\pi^2 v_1^2 + v_3^2}) e^{i\Omega v_1 v_3} Y_0 \Psi(\theta; v_1, Y_0, v_3) \]

with

\[ \alpha(\theta; v_1, v_3) = v_1 \cos \theta - \Omega(v_1, v_3) \sin \theta \]

\[ \beta(\theta; v_1, v_3) = v_3 \sin \theta + \Omega(v_1, v_3) \cos \theta \]

\[ \Omega(v_1, v_3) = \text{Re}(\mu(v_1, v_3)) \]

(34)

\[ \mu(v_1, v_3) = \frac{k}{2\pi} \tan \frac{1}{2} \sqrt{k^2 - 4\pi^2 v_1^2 + v_3^2}. \]

ACKNOWLEDGMENT

The authors wish to thank Dr. M. Gautherie and Dr. J. L. Guerquin-Kern (Laboratoire de Thermologie Biomédicale, Faculté de Médecine of Strasbourg, France) for discussions and contribution to the experiments on animal organs. The cooperation with the Société d’Etude du Radiant is greatly appreciated. The authors wish to thank Dr. Lesselier for his helpful comments on the manuscript.
REFERENCES

Christian Pichot was born in Rozay-en-Brie, France, on March 6, 1951. He received the M.S. degree from the University of Nice, France, in 1974, and the Doctorat Third Cycle and the Doctorate es Sciences degrees from the University of Paris XI (Orsay) in 1977 and 1982, respectively.

He joined the Groupe d’Electromagnetisme du Laboratoire des Signaux et Systèmes in 1978. He is presently a Chargé de Recherche at the Centre National de la Recherche Scientifique (CNRS). His research activities are concerned with scattering, direct and inverse, and guided wave problems in inhomogeneous media. He received the Microwave Prize of the European Microwave Conference in Nürnberg in 1983.

Luis Jofre was born in Mataró, Spain, in 1956. He received the Ingeniero and Doctor Ingeniero degrees in Telecommunication Engineering, both from the Universitat Politecnica de Barcelona (UPB), in 1978 and 1982, respectively.

In 1978 he was employed as Research Assistant in the Electrophysics Department at U.P.B. where he worked on analysis and near-field measurement of antennas. During 1981 he joined the Ecole Supérieure d’Electricité, where he was involved in microwave imaging techniques for biomedical applications. Since 1982 he is an Associate Professor at he U.P.B. where he is engaged in research in the areas of electromagnetic wave diffraction and antennas, with specific emphasis on microwave holography and near-field techniques. He received the Microwave Prize of the European Microwave Conference in Nürnberg in 1983.

Guillaume Peronnet was born in Grenoble, France, in 1956. He received the Engineer degree from Ecole Supérieure d’Electricité in 1979 with radio communications specialization.

Since 1980 he has been a Chef de Travaux Adjoint in ESF where he is engaged in research in electromagnetism and particularly in microwave imaging. He received the Microwave Prize of the European Microwave Conference in Nürnberg in 1983.
