[farre | teniente | urpi]@lsi.upc.es

Abstract. We present a method that checks Query Containment for queries with negated IDB predicates. Existing methods either deal only with restricted cases of negation or do not check actually containment but uniform containment, which is a sufficient but not necessary condition for containment. Additionally, our queries may also contain equality, inequality and order comparisons. The generality of our approach allows our method to deal straightforwardly with query containment under constraints. Our method is sound and complete both for success and for failure and we characterize the databases where these properties hold. We also state the class of queries that can be decided by our method.

1 Introduction

Query Containment (QC) is the problem concerned with checking whether the answers that a query obtains are a subset of the answers obtained by another query for every database. QC Checking is applied as a base technique in several contexts: query optimization [Ull89], rewriting queries using views [Hal01], detecting independence of queries from database updates [LS93], constraint verification [GSUW94, LR98], etc.

QC was first studied for the class of conjunctive queries [CM77, CR97]. QC of conjunctive queries with order comparisons was studied in [Klu88, LS93, Ull97]. Conjunctive QC with safe negated EDB atoms was investigated in [LS93, Ull97, WL03]. EDB stands for extensional database, that is, the database’s stored relations whereas IDB means intensional database, that is, the relations constructed by deductive rules.

The methods that deal with negated IDB subgoals can be classified into two different approaches. The first one is taken by those methods that check QC for query classes where negation is used in a restrictive way [HMSS01, LS95]. The second approach is represented by those methods that do not check “true” QC but another related property called Uniform QC [LS93, DS96], which is a sufficient but not necessary condition for QC [Sag88].

When considering integrity constraints, the containment relationship between two queries does not need to hold for any state of the database but only for those that satisfy the integrity constraints. This idea is captured by the notion of Query Containment under Constraints (QCuC). QCuC checking was investigated for conjunctive queries under integrity constraints expressing functional dependencies [ASU79, JK84], inclusion dependencies [JK84] or object database schemas [Cha92, BJNS94, LS97]; for datalog queries, without negation, under integrity constraints expressing tuple-generating dependencies was addressed in [Sag88, DS96] by taking the uniform containment approach; and also in the context of hybrid systems combining conjunctive or datalog queries and constraints expressed in a Description Logic language [BJNS94, LR96, CDL98].

In [FTU99] we sketched a method, named Constructive Query Containment method (CQC for short), to check “true” QC and QCuC in the presence of negation on IDB subgoals. Intuitively, the aim of our CQC method was to construct a counterexample that proves that there is no QC (or QCuC). This method
used different Variable Instantiation Patterns (VIPs), according to the syntactic properties of the queries and the databases considered in each test. Such a customization only affects the way that the facts to be part of the counterexample are instantiated. The aim was to prune the search of the counterexample by generating only the relevant facts.

We extend here our previous work by:
- providing not just an intuitive idea but also the full formalization of the CQC method.
- proving two additional theorems that hold when there are no recursively defined IDB relations: failure soundness, which guarantees that containment holds if the method terminates without building any counterexample; and failure completeness, which ensures that if containment holds between two queries then our method fails finitely (and terminates).
- ensuring termination when checking containment for conjunctive queries with safe EDB negation and built-in literals.
- showing that the CQC method is not less efficient than other methods that deal with conjunctive queries with or without safe EDB negation. We propose an additional VIP, the simple VIP, to perform such a comparison.
- decomposing the General VIP in two: the discrete order VIP and the dense order VIP that allow us to deal with built-in literals assuming both discrete and dense order domains.

It follows from these new results that the method we propose here improves previously proposed algorithms since it provides an efficient decision procedure for known decidable cases and can also be applied for more general forms of queries that were not handled by previous algorithms. In these more general cases our method is semidecidable because it can not be guaranteed termination under the presence of infinite counterexamples. Nevertheless, if there is a finite counterexample our method finds it and terminates and if containment holds our method fails finitely and terminates.

Section 2 sets the base concepts used through the paper. In Section 3, we introduce our method and Section 4 formalizes it. In Section 5, we present the main correctness results of our method. In Section 6, we discuss the decidability issues regarding our method. In Section 7, we compare our method with related work. The paper ends with the conclusions, Section 8, and references. For a more detailed formalization and detailed proofs, we refer to [FTU02].

2 Base Concepts

A deductive rule has the form:

\[ p(\bar{X}) \leftarrow r_1(\bar{X}_1) \land \ldots \land r_m(\bar{X}_m) \land \neg r_{m+1}(\bar{Y}_1) \land \ldots \land \neg r_n(\bar{Y}_n) \land C_1 \land \ldots \land C_l \]

where \( p \) and \( r_1, \ldots, r_m \) are predicate (also called relation) names. The atom \( p(\bar{X}) \) is called the head of the rule, and \( r_1(\bar{X}_1), \ldots, r_m(\bar{X}_m), \neg r_{m+1}(\bar{Y}_1), \ldots, \neg r_n(\bar{Y}_n) \) are the positive and negative ordinary literals in the body of the rule. The tuples \( \bar{X}, \bar{X}_1, \ldots, \bar{X}_n, \bar{Y}_1, \ldots, \bar{Y}_n \) contain terms, which are either variables or constants. Each \( C_i \) is a built-in literal in the form of \( A_1 \theta A_2 \), where \( A_1 \) and \( A_2 \) are terms. Operator \( \theta \) is \( <, =, >, =, \leq, \lneq \) or \( ? \). We require that every rule be safe, that is, every variable appearing in \( \bar{X}, \bar{Y}_1, \ldots, \bar{Y}_n, C_1, \ldots \) or \( C_l \) must also appear in some \( \bar{X}_i \).

The predicate names in a deductive rule range over the extensional database (EDB) predicates, which are the relations stored in the database, and the intensional database (IDB) predicates (like \( p \) above), which are the relations defined by the deductive rules. EDB predicates must not appear in the head of a deductive rule.

A set of deductive rules \( P \) is hierarchical if there is a partition \( P = P_1 \cup \ldots \cup P_n \) such that for any ordinary atom \( r(\bar{X}) \) occurring positively or negatively (as \( \neg r(\bar{X}) \)) in the body of a clause in \( P_i \), the definition of \( r \) is contained within \( P_j \) with \( j < i \). Note that a hierarchical set of deductive rules contains no recursive definitions about IDB relations.
A condition has the denial form of:

\[ \langle r_1(X_1) \land \ldots \land r_n(X_n) \land \neg r_{n+1}(\bar{Y}_1) \land \ldots \land \neg r_m(\bar{Y}_m) \land C_1 \land \ldots \land C_i \rangle \]

where \( r_1(X_1), \ldots, r_n(X_n), \neg r_{n+1}(\bar{Y}_1), \ldots, \neg r_m(\bar{Y}_m) \) are the (positive and negative) ordinary literals; and \( C_1, \ldots, C_i \) are built-in literals. If \( \bar{Z} \) is the set of the variables occurring in \( \bar{Y}_1, \ldots, \bar{Y}_m, C_1, \ldots, C_i \), we require that each variable in \( \bar{Z} \) must also occur in some \( X_i \). Roughly, a condition in denial form expresses a prohibition: a conjunction of facts (literals in the body) that must not hold on the database all at once. Therefore, a condition is violated (not satisfied), whenever \( \exists \bar{Z} (r_1(X_1) \land \ldots \land r_n(X_n) \land \neg r_{n+1}(\bar{Y}_1) \land \ldots \land \neg r_m(\bar{Y}_m) \land C_1 \land \ldots \land C_i) \) is true on the database.

A query \( Q \) is a finite set of deductive rules that defines a dedicated \( n \)-ary query predicate \( q \). Without loss of generality, other predicates than \( q \) appearing in \( Q \) are EDB or IDB predicates.

A query \( Q_1 \) is contained in a query \( Q_2 \), denoted by \( Q_1 \subseteq Q_2 \), if the set of answers of \( Q_1(D) \) is a subset of those of \( Q_2(D) \) for any database \( D \). Moreover, \( Q_1 \) is contained in \( Q_2 \) wrt IC, denoted by \( Q_1 \subseteq_{IC} Q_2 \), if the set of answers of \( Q_1(D) \) is a subset of those of \( Q_2(D) \) for any database \( D \) satisfying a finite set IC of conditions (integrity constraints).

### 3 The Constructive Query Containment (CQC) Method

The containment relationship between two queries must hold for the whole set of possible databases in the general case. A suitable way of checking QC is to check the lack of containment, that is, to find just one database where the containment relationship that we want to check does not hold: \( Q_1 \) is not contained in \( Q_2 \), written \( Q_1 \nsubseteq Q_2 \), if there is at least one database \( D \) such that \( Q_1(D) \nsubseteq Q_2(D) \).

Given \( Q_1 \) and \( Q_2 \), two queries, the CQC method is addressed to construct the extensional part of a database (EDB) where the containment relationship does not hold. It requires two main inputs: the goal to attain and the set of conditions to enforce. Initially, the goal is defined \( G_0 = \langle q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \rangle \), meaning that we want to construct a database where \( (X_1, \ldots, X_n) \) could be instantiated in such a way that \( q_1(X_1, \ldots, X_n) \) is true and \( q_2(X_1, \ldots, X_n) \) is false. The set of conditions to enforce is \( F_0 = \emptyset \), meaning that there is no initial integrity constraint to take care about.

When considering a set IC of integrity constraints, we say that \( Q_1 \) is not contained in \( Q_2 \) wrt IC, written \( Q_1 \nsubseteq_{IC} Q_2 \), if there is at least one database \( D \) satisfying IC, such that \( Q_1(D) \nsubseteq Q_2(D) \). In this case, the EDB that the CQC method has to construct to refute the containment relationship must also satisfy the conditions in IC. This is guaranteed by making the initial set of conditions to enforce \( F_0 = IC \) together with the goal \( G_0 = \langle q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \rangle \).

#### 3.1 Example: \( Q_1 \subseteq Q_2 \)

The following example is adapted from the one in [FTU99] by introducing double negation on IDB predicates. It allows illustrating the main ideas of our method and to show its behavior under these complex cases. Let \( Q_1 \) and \( Q_2 \) be two queries:

\[
\begin{align*}
Q_1 &= \{ \text{sub}(X) \leftarrow \text{emp}(X) \land \neg \text{chief}(X) \} \\
Q_2 &= \{ \text{sub}(X) \leftarrow \text{emp}(X) \land \neg \text{boss}(X) \}
\end{align*}
\]

where \( \text{emp} \) is an EDB predicate and \( \text{chief} \) and \( \text{boss} \) are IDB predicates defined by a set \( DR \) of deductive rules:

\[
\begin{align*}
DR &= \{ \text{boss}(X) \leftarrow \text{worksFor}(Z, X) \\
&\quad \text{chief}(X) \leftarrow \text{worksFor}(Y, X) \land \neg \text{boss}(Y) \}
\end{align*}
\]

where \( \text{worksFor} \) is another EDB predicate.
Intuitively, we can see that $Q_1$ is less restrictive than $Q_2$ because $Q_2$ does not retrieve those employees having anyone working for them, while $Q_1$ allows retrieving employees having some boss working for them. Hence, we can find a database containing EDB relations such as $emp(\text{joan})$, $worksFor(\text{mary}, \text{joan})$ and $worksFor(\text{ann}, \text{mary})$, where $\neg sub_1(\text{joan})$ is true but $\neg sub_2(\text{joan})$ is false ($chief(\text{joan})$ is false because $boss(\text{mary})$ is true whereas $boss(\text{joan})$ is true). Therefore, $Q_1$ is not contained in $Q_2$. Note that an even smaller EDB containing just $emp(\text{joan})$ and $worksFor(\text{joan}, \text{joan})$ would have lead us to the same conclusion.

A CQC-derivation that constructs an EDB that proves $Q_1 \subseteq Q_2$ are shown in figure 3.1. Each row on the figure corresponds to a CQC-node that contains the following information (columns):

1. The goal to attain: the literals that must be made true by the EDB under construction. When the goal is $[]$ it means that no literal needs to be satisfied. Here, the initial CQC-node contains the goal $G_0 = \leftarrow sub_1(X) \land \neg sub_2(X)$. That is, we want the CQC method to construct a database where exists at least a constant $k$ such that both $sub_1(k)$ and $\neg sub_2(k)$ are true.
2. The conditions to be enforced: the set of conditions that the constructed EDB is required to satisfy. Recall that a condition is violated whenever all of its literals are evaluated as true. Here, the initial CQC-node contains the set of conditions to enforce $F_0 = \emptyset$.
3. The EDB under construction. The initial CQC-Nodes has always an empty EDB.
4. The conditions to be maintained: the set containing those conditions that are known to be satisfied in the current CQC-node and that must remain satisfied until the end of the CQC-derivation. Initial CQC-Nodes have always this set empty.
5. The account of constants introduced in the current and/or the ancestor CQC-nodes to instantiate the EDB facts in the EDB under construction. Initially, such a set contains always the constants appearing already in $DR\cup Q_1\cup Q_2\cup G_0\cup F_0$.

The transition between two consecutive CQC-nodes, i.e. between an ancestor node and its successor, is a CQC-step that is performed by applying a CQC-expansion rule to a selected literal of the ancestor CQC-node. The selection of literals in the CQC-derivation of figure 3.1 is nearly arbitrary: the only necessary criterion is to avoid picking a non-ground negative-ordinary or built-in literal. In figure 3.1, the CQC-steps are labeled with the name of the CQC-expansion rule that is applied and the selected literal in each step is underlined. We refer to Section 4.2 for a proper formalization of the CQC-expansion rules.

The first step unfolds the selected literal, the IDB atom $sub_1(X)$ from the goal part, by substituting it with the body of its defining rule. At the second step, the selected literal from the goal part is $emp(X)$, which is a positive EDB literal. To get a successful derivation, i.e. to obtain an EDB satisfying the initial goal, $emp(X)$ must be true on the constructed EDB. Hence, the method instantiates $X$ with a constant and includes the new ground EDB fact in the EDB under construction. The procedure assigns an arbitrary constant to $X$, e.g. 0. So $emp(0)$ is the first fact included in the EDB under construction.

$\neg chief(0)$ is the selected literal in step 3. To get success for the derivation, $chief(0)$ must not be true on the EDB. This is guaranteed by adding $\leftarrow chief(0)$ as a new condition to be enforced. Step 4 is similar to step 3, yielding $\leftarrow sub_2(0)$ to be considered as another condition to be enforced. After performing this later step, we get a CQC-node with a goal like $[]$. However, the work is not done yet, since we must ensure that the two conditions $\leftarrow sub_2(0)$ and $\leftarrow chief(0)$ are not violated by the current EDB. In other words, we must make both $chief(0)$ and $sub_2(0)$ false.

Step 5 unfolds the selected literal $chief(0)$ from one of the two conditions, getting $\leftarrow worksFor(Y, 0) \land \neg boss(Y)$ as a new condition that replaces $\leftarrow chief(0)$. At least one of the two literals of this condition must be false. In step 6, the selected literal is the positive EDB literal is $worksFor(Y, 0)$. Since it matches with no EDB atom in the EDB under construction, $worksFor(Y, 0)$ is false and, consequently, the whole condition $\leftarrow worksFor(Y, 0) \land \neg boss(Y)$ is not violated by the current EDB. For this reason, such a condition is moved from the set of conditions to enforce to the set of conditions to maintain.
Step 7 unfolds the selected IDB atom \textit{sub}_2(0) from the remaining condition to enforce. The EDB atom \textit{emp}(0) is the selected literal in step 8. Since \textit{emp}(0) is also present in the EDB under construction, it cannot be false. So this literal is dropped from the condition because it does not help to enforce the condition. In step 9 the selected literal is the negative literal \textit{¬boss}(0). Since it is the only literal of the condition, it must be made false necessarily. So \textit{boss}(0) becomes a new (sub)goal to achieve and is transferred, thus, to the goal part.

</tbody>
</table>

Fig. 3.1.

Step 10 unfolds the selected literal \textit{boss}(0) from the goal part as in step 1. \textit{worksFor}(Z, 0) is the selected literal in step 11. As in step 2, the method should instantiate \textit{Z} with a constant. In this case, the chosen constant is 0 again, so \textit{worksFor}(0, 0) is added to the EDB under construction. Moreover, the condition \( \leftarrow \text{worksFor}(Y, 0) \wedge \neg \text{boss}(Y) \) is moved back to the set of conditions to enforce to avoid that the new inclusion of \textit{worksFor}(0, 0) in the EDB violates it.

In step 12, the selected literal is the positive EDB literal is \textit{worksFor}(Y, 0) from the remaining condition to enforce. Now, it matches with the current contents of the EDB with \( Y = 0 \). As in step 8, such a literal is dropped from the condition. However, the whole condition \( \leftarrow \text{worksFor}(Y, 0) \wedge \neg \text{boss}(Y) \) is
moved again to the set of conditions to maintain in order to prevent further inclusions of new facts about \textit{worksFor} in the EDB from violating it.

Steps 13 and 14 are identical to steps 9 and 10. In step 15, the constant 0 is selected again to instantiate \textit{worksFor}(Z, 0). Since \textit{worksFor}(0, 0) is already included in the EDB, there is no need to transfer back any condition from the set of conditions to maintain to the set of conditions to enforce.

The CQC-derivation ends successfully since it reaches a CQC-node where the goal to attain is \{\} and the set of conditions to satisfy is empty. In other words, we can be sure that its EDB, \{\textit{emp}(0), \textit{worksFor}(0, 0)\}, contains a set of facts that makes the database satisfy the goals and conditions of all preceding CQC-nodes, including, naturally, the first CQC-node. Then we conclude \(Q_1 \subseteq Q_2\).

### 3.2 Variable Instantiation Patterns

When a CQC-derivation terminates successfully, we obtain a proof, the constructed EDB, which shows that the containment relationship is not true. On the contrary, when a derivation ends unsuccessfully, that is, it terminates but it fails to construct a counterexample, we cannot conclude that containment holds based on a single result. Then the question is how many derivations must be considered before achieving a reliable conclusion. Indeed, rather than the account of all possible derivations, the real point is to know how many variable instantiation alternatives must be considered when adding new facts to the EDB under construction. Since the set of possible combinations of alternative constant assignments to instantiate EDB facts is what determines the set of different EDBs that can be constructed.

The aim of the CQC method is to test only the variable instantiations that are relevant without losing completeness. The “strategy” for instantiating the EDB facts to be included in the EDB under construction is connected to, indeed it is inspired by, the concept of \textit{canonical databases} found in [Klu88, LS93, Ull97]. This concept is based on the idea that it is not necessary to check the whole (infinite) set of possible EDBs to prove containment but only a (finite) subset of them, the set of canonical EDBs. In this way, if it is proved that a containment relationship holds on any canonical EDB, then QC holds for any EDB. The soundness of this approach is guaranteed by proving that any possible EDB is represented by one canonical EDB and that this correspondence preserves the containment relationship.

In contrast to [Klu88, LS93, Ull97], our method does not need to generate the whole set of canonical databases in advance. Our containment tests end as soon as a successful a CQC-derivation leading to a canonical counterexample is found. It is only in the worst case, when no counterexample exists, when the complete tree of failed CQC-derivations will have test every canonical database. However, even in this case, recreating completely each canonical database may not be always required before discarding it since, for instance, it is early detected that some condition is violated with no possible repair.

Since the canonical databases to be taken into account depend on the concrete subclass of queries that are considered, we distinguish three different \textit{variable instantiation patterns}, VIPs for shorthand. Each of them defines how the CQC method has to instantiate the EDB facts to be added to the EDB under construction. The following three VIPs are formalized in Appendix A: \textit{Simple VIP}, \textit{Negation VIP} (as considered in [FTU99]), \textit{Dense Order VIP} and \textit{Discrete Order VIP}.

The CQC method uses the \textit{Simple VIP} when checking containment but not QC under constraints. Moreover, the deductive rules defining query predicates as well as IDB predicates must satisfy the following conditions: they must not have any negative or built-in literal\(^1\) in their rule bodies; they must not have constants in their heads; and they must not have any variable appearing twice or more times in their heads. According to the Simple VIP, each distinct variable is bound to a distinct new constant.

The CQC method uses the \textit{Negation VIP} when checking QCUC or when checking containment under the presence of negated IDB subgoals, negated EDB subgoals and/or (in)equality comparisons (=, ?). In

\(^1\) However, note that if a deductive rule has a literal of the form \(z = k\) or \(z = x\) in its body such that \(z\) does not appear in the head, then that literal can be omitted by replacing each occurrence of \(z\) in the rule body by \(k\) or \(x\), respectively.
any case, order comparisons (≠, =, >, =), are not allowed. EDBs generated and tested with this VIP correspond to the canonical EDBs considered in [LS93, Ull97] for the conjunctive query case with negated EDB subgoals. The intuition behind this VIP is clear: Each new variable appearing in a EDB fact to be grounded is instantiated with either some constant previously used or a constant never used before. This is the pattern used in the CQC-derivation showed in the figure 3.1.

The other two VIPs, Dense Order VIP and Discrete Order VIP, are applied when there are order comparisons (≠, =, >, =) in the deductive rules, with or without negation. In this case, each distinct variable must be bound to a constant according to either a former or a new location in the total linear order of constants introduced previously [Klu88, LS93, NSS98, Ull97]. The election between to apply either the Dense Order VIP or the Discrete Order VIP depends on whether the comparisons are interpreted on a dense order (e.g. rational and real numbers) or on a discrete order (e.g. integer numbers).

4 Formalization Of The CQC Method

Let \( Q_1 \) and \( Q_2 \) be two queries, \( DR \) the set of deductive rules defining the database IDB relations and \( IC \) a finite set of conditions expressing the database integrity constraints. If the CQC method performs a successful CQC-derivation from \( \left( \left\langle q_1(X_1, ..., X_n) \wedge \neg q_2(X_1, ..., X_n) \right\rangle \emptyset \emptyset K \right) \) to \( \left( \left\langle \emptyset \emptyset T C K' \right\rangle \right) \), then \( Q_1 \subseteq Q_2 \), where \( K \) is the set of constants appearing in \( DR \cup Q_1 \cup Q_2 \). Moreover, if the CQC method performs a successful CQC-derivation from \( \left( \left\langle q_1(X_1, ..., X_n) \wedge \neg q_2(X_1, ..., X_n) \right\rangle IC \emptyset \emptyset K' \right) \) to \( \left( \left\langle \emptyset \emptyset T C K'' \right\rangle \right) \), then \( Q_1 \subseteq IC Q_2 \), where \( K'' \) is the set of constants appearing in \( DR \cup Q_1 \cup Q_2 \cup IC \).

CQC-derivations start from a 5-tuple \( (G_0, F_0, T_0, C_0, K_0) \) consisting of the goal \( G_0 = \left\langle q_1(X_1, ..., X_n) \wedge \neg q_2(X_1, ..., X_n) \right\rangle \emptyset \emptyset K \), the initially-empty EDB \( T_0 = \emptyset \), the empty set of conditions to maintain \( C_0 = \emptyset \) and the empty set of constants appearing in \( DR \cup Q_1 \cup Q_2 \cup IC \).

A successful CQC-derivation reaches a 5-tuple \( (G_n, F_n, T_n, C_n, K_n) = \left( \left\langle \emptyset \emptyset T C K' \right\rangle \right) \), where the empty goal \( G_n = \emptyset \) means that we have reached the goal \( G_0 \) we were looking for. The empty set \( F_n = \emptyset \) means that no condition is waiting to be satisfied. \( T_n = T \) is an EDB that satisfies \( G_n \) as well as \( F_0 \), \( C_n = C \) is a set of conditions recorded along the derivation and that \( T \) also satisfies, \( K_n = K' \) is the set of constant values appearing in \( DR \cup Q_1 \cup Q_2 \cup IC \).

On the contrary, if every “fair” CQC-derivation starting from \( \left( \left\langle q_1(X_1, ..., X_n) \wedge \neg q_2(X_1, ..., X_n) \right\rangle \emptyset \emptyset K \right) \) is finite but does not reach \( \left( \left\langle \emptyset \emptyset T C K' \right\rangle \right) \), it will mean that no EDB satisfies the goal \( G_n = \left\langle q_1(X_1, ..., X_n) \wedge \neg q_2(X_1, ..., X_n) \right\rangle \) together with the set of conditions \( F_0 = \emptyset \cup IC \), concluding that \( Q_1 \not\subseteq Q_2 \) if \( Q_1 \not\subseteq IC Q_2 \). Section 5 below provides the complete results and proofs regarding the soundness and completeness of the CQC method.

4.1 CQC-Nodes, CQC-Trees and CQC-Derivations

Let \( Q_1 \) and \( Q_2 \) be two queries, \( DR \) be the set of deductive rules defining the database IDB relations and \( IC \) be a finite set of conditions expressing the database integrity constraints. A CQC-node is a 5-tuple of the form \((G, F, T, C, K)\), where \( G \) is a goal to attain; \( F \) is a set of conditions to enforce; \( T \) is a set of ground EDB atoms, an EDB under construction; \( C \) is a set of conditions that are currently satisfied in \( T \) and must be maintained; and \( K \) is the set of constants appearing in \( R = DR \cup Q_1 \cup Q_2 \cup IC \) and \( T \).

A CQC-tree is inductively defined as follows:

1. The tree consisting of the single CQC-node \((G_0, F_0 \emptyset K)\) is a CQC-tree.

2. Let \( E \) be a CQC-tree, and \((G_n, F_n, T_n, C_n, K_n)\) a leaf CQC-node of \( E \) such that \( G_n \not\subseteq IC \) or \( F_n \not\subseteq IC \). Then the tree obtained from \( E \) by appending one or more descendant CQC-nodes according to a CQC-expansion rule applicable to \((G_n, F_n, T_n, C_n, K_n)\) is again a CQC-tree.

It may happen that the application of a CQC-expansion rule on a leaf CQC-node \((G_n, F_n, T_n, C_n, K_n)\) does not obtain any new descendant CQC-node to be appended to the CQC-tree because some necessary
constraint defined on the CQC-expansion rule is not satisfied. In such a case, we say that \( (G_i \leftarrow F_i \land C_i \land K_i) \) is a failed CQC-node.

Each branch in a CQC-tree is a CQC-derivation consisting of a (finite or infinite) sequence \( (G_0 \leftarrow F_0 \land C_0 \land K_0), (G_1 \leftarrow F_1 \land C_1 \land K_1), \ldots \) of CQC-nodes.

A CQC-derivation is finite if it consists of a finite sequence of CQC-nodes; otherwise it is infinite. A CQC-derivation is successful if it is finite and its last (leaf) CQC-node has the form \( [ \emptyset \leftarrow T_n \land C_n \land K_n] \). That is, both the goal to attain and the set of conditions to satisfy are empty. A CQC-derivation is failed if it is finite and its last (leaf) CQC-node is failed.

A CQC-tree is successfully when at least one of its branches is a successful CQC-derivation. A CQC-tree is finitely failed when each one of its branches is a failed CQC-derivation.

</tr>
</tbody>
</table>

only if \( L \) is evaluated true.

4.2 The CQC-Expansion Rules

The nine CQC-expansion rules are listed in tables 4.1 and 4.2. For the sake of notation, if \( G_i = \leftarrow L_1 \land \ldots \land L_{p-1} \land L_p \land L_{p+1} \land \ldots \land L_m \) then \( G_i \land \neg \bot = \leftarrow L_1 \land \ldots \land L_{p-1} \land L_{p+1} \land \ldots \land L_m \). If \( G_i = \leftarrow L_1 \land \ldots \land L_m \) then \( G_i \land \neg \bot = \leftarrow L_1 \land \ldots \land L_m \land \neg p(\bar{x}) \).

The application of a CQC-expansion rule on a given CQC-node \( (G_i \leftarrow F_i \land C_i \land K_i) \) may result in none, one or several alternative (branching) descendant CQC-nodes depending on the selected literal \( P(U_i) = \bot \). Here, \( J_i \) is either the goal \( G_i \) or any of the conditions \( F_{i,j} \) in \( F_i \). \( L \) is selected according to a safe computation rule \( P \) [Llo87], which selects negative and built-in literals only when they are fully grounded. To guarantee that such literals are sooner or later selected we require deductive rules and goals to be safe.
Once a literal is selected, only one of the CQC-expansion rules can be applied. We distinguish two classes of rules: A-rules and B-rules. A-rules are those where the selected literal belongs to the goal $G_i$. Instead, B-rules correspond to those where the selected literal belongs to any of the conditions $F_{ij}$ in $F_i$. Inside each class of rules, they are differentiated with respect to the type of the selected literal.

In each CQC-expansion rule, the part above the horizontal line presents the CQC-node to which the rule is applied. Below the horizontal line is the description of the resulting descendant CQC-nodes. Vertical bars separate alternatives corresponding to different descendants. Some rules like A1, A5, B2 and B4 include also an “only if” condition that constraints the circumstances under which the expansion is possible. If such a condition is evaluated false, the CQC-node to which the rule is applied becomes a failed CQC-node.

Finally, note that three CQC-expansion rules, namely A1, B1 and B2, use the resolution principle as is defined in [Llo87].

<table>
<thead>
<tr>
<th>Table 4.2. CQC-expansion rules: B#-rules.</th>
</tr>
</thead>
</table>

**B1)** $P(F_{ij}) = d(\bar{X})$ is a positive IDB atom:

\[
\begin{align*}
& (G_i \{ F_{ij} \} \cup F_i T_i C_i K_i) \\
& (G, S \cup F_i T_i C_i K_i)
\end{align*}
\]

where $S$ is the set of all resolvents $S_u$ for clauses in $R$ and $F_{ij}$ on $d(\bar{X})$. $S$ may be empty.

**B2)** $P(F_{ij}) = b(\bar{X})$ is a positive EDB atom:

\[
\begin{align*}
& (G_i \{ F_{ij} \} \cup F_i T_i C_i K_i) \\
& (G, S \cup F_i T_i C_{i+1} K_i)
\end{align*}
\]

only if $[] \notin S$.

$C_{i+1} = C_i$ if $\bar{X}$ contains no variables and $b(\bar{X}) \in T_i$; otherwise, $C_{i+1} = C_i \cup \{ F_{ij} \}$

$S$ is the set of all resolvents of clauses in $T_i$ with $F_{ij}$ on $b(\bar{X})$. $S$ may be empty, meaning that $b(\bar{X})$ cannot be unified with any atom in $T_i$.

**B3)** $P(F_{ij}) = \neg p(\bar{X})$ is a ground negative ordinary literal:

\[
\begin{align*}
& (G_i \{ F_{ij} \} \cup F_i T_i C_i K_i) \\
& (G, \{ F_i p(\bar{X}) \} \cup F_i T_i C_i K_i)
\end{align*}
\]

only if $F_{ij} \neg p(\bar{X}) \neq []$.

**B4)** $P(F_{ij}) = L$ is a ground built-in literal that is evaluated true:

\[
\begin{align*}
& (G_i \{ F_{ij} \} \cup F_i T_i C_i K_i) \\
& (G, [F_i \{ L \} \cup F_i T_i C_i K_i])
\end{align*}
\]

only if $F_i \neg L \neq []$.

**B5)** $P(F_{ij}) = L$ is a ground built-in literal that is evaluated false:

\[
\begin{align*}
& (G_i \{ F_{ij} \} \cup F_i T_i C_i K_i) \\
& (G, F_i T_i C_i K_i)
\end{align*}
\]

### 5 Correctness Results For The CQC Method

In this Section, we summarize and sketch the new proofs of correctness of the CQC method. We refer the reader to [FTU02] for the detailed proofs. We also state the class of queries that can be actually decided by the CQC method. Before proving these results, we need to make explicit the model-theoretic semantics to with respect those results are established.
We view the CQC method as an extension of SLDNF-resolution [Cla77, Llo87]. However, there is an important difference between both methods. When applying SLDNF-resolution, the input set of information, the logic program and the goal to attain, is closed, that is, neither new facts nor rules are added on behalf of a SLDNF-resolution procedure. Instead, the CQC method enforces the addition of new information, in terms of EDB facts, on behalf of the method, if it is considered necessary for assuring the satisfaction of the non-containment goal. This key difference will be reflected on the semantics that founds each method.

The model-theoretic counterpart of the procedural semantics of SLDNF-resolution is Clark’s completion [Cla77, Llo87]. In this way, the soundness and completeness results of SLDNF-resolution are established with respect to the semantics of the completed logic programs taken as a input. In a similar way, we introduce the notion of partial completion of deductive rules to provide a model-theoretic foundation to prove the soundness and completeness of the CQC method.

Let \( R \) be a set of deductive rules. We define the partial completion of \( R \), denoted by \( \text{pComp}(R) \), as the collection of completed definitions [Cla77, Llo87] of IDB predicates in \( R \) together with an equality theory. This later one includes a set of axioms stating explicitly the meaning of the built-in predicate \( = \) introduced in the completed definitions.

Our partial completion is defined similarly to Clark’s completion, \( \text{Comp}(R) \), but without including the axioms of the form \( \forall X (\neg b_i(X)) \) for each predicate \( b_i \) which only appear in the body of the clauses in \( R \). We assume that these predicates are EDB predicates that, obviously, are not defined in \( R \).

If \( Q_1 \) and \( Q_2 \) are two queries, \( \text{DR} \) is the set of deductive rules defining the database IDB relations and \( IC \) be a finite set of conditions expressing the database integrity constraints, we consider that problem of knowing whether \( Q_1 \ S \ Q_2 \ (Q_1, S_{IC} Q_2) \) is equivalent to the problem of proving that \( \text{pComp}(R | IC) \) is a model for \( \forall X_1 \ldots X_n \ q_1(X_1, \ldots, X_n) \rightarrow q_2(X_1, \ldots, X_n) \) is true, where \( R = \text{DR} \cup Q_1 \cup Q_2 \). If we define the initial goal \( G_0 = \leftarrow q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \) then testing \( Q_1 \ S \ Q_2 \ (Q_1, S_{IC} Q_2) \) is equivalent to proving \( \text{pComp}(R | IC) \) in \( G_0 \). This proof is tackled by the CQC method, which tries to refute \( \text{pComp}(R | IC) \) by constructing an EDB \( T \) such that \( R(T) \) is a model for \( \text{pComp}(R | IC) \cup \{ X_1 \ldots X_n q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \} \).

In the following theorems, let \( G_0 = \leftarrow q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \) be the initial goal, \( F_0 = \emptyset [IC] \) be the initial set of conditions to enforce and \( K \) be the set of constants appearing in \( \text{DR} \cup Q_1 \cup Q_2 \cup F_0 \).

Before proving results related to failure of the CQC method, we review the results related to finite success already stated in [FTU99].

**Theorem 5.1 (Finite Success Soundness)**

If there exists a finite successful CQC-derivation starting from \( (G_0 \ F_0 \emptyset \ K) \) then \( Q_1 \subset Q_2 \ (Q_1, S_{IC} Q_2) \) provided that \( \{ G_0 \} \cup F_0 \cup \text{DR} \cup Q_1 \cup Q_2 \) is safe and hierarchical.

**Theorem 5.2 (Finite Success Completeness)**

If \( Q_1 \subset Q_2 \ (Q_1, S_{IC} Q_2) \) then there exists a successful CQC-derivation from \( (G_0, F_0 \emptyset \ K) \) to \( (\emptyset \emptyset \emptyset C K) \) provided that \( \{ G_0 \} \cup F_0 \cup \text{DR} \cup Q_1 \cup Q_2 \) is safe and either hierarchical or strict-stratified [CL89].

These results ensure that, in the absence of recursive IDB predicates, if the method builds a finite counterexample, then containment does not hold (Theorem 5.1); and that if there exists a finite counterexample, then our method finds it and terminates (Theorem 5.2). We extend these results by assessing the properties regarding failure of our method. In this sense, we prove failure soundness (Theorem 5.3) which guarantees that if the method terminates without building any counterexample then containment holds; and failure completeness (Theorem 5.5) which states that if containment holds between two queries then our method fails finitely.

**Theorem 5.3 (Failure Soundness)**

If there exists a finitely failed CQC-Tree rooted at \( (G_0, F_0 \emptyset \emptyset K) \) then \( Q_1 \subset Q_2 \ (Q_1, S_{IC} Q_2) \) provided that the deductive rules and conditions in \( \text{DR} \cup Q_1 \cup Q_2 [\cup IC] \) are safe.

The proof of Theorem 5.3 is made by using the principle of contradiction and may be intuitively explained as follows. Let us suppose that we have a finitely failed CQC-tree but \( Q_1 \subset Q_2 \ (Q_1, S_{IC} Q_2) \). If \( Q_1 \)
A CQC-derivation is open when it is not failed. That is, when the derivation is either infinite or finite with its last (leaf) CQC-node having the form of (\{\} \circ T_n C_n K_n). A CQC-derivation \( \theta \) is saturated for the CQC-expansion Rules if for every CQC-node \((G, F, T, C, K)\) in \( \theta \) the following properties hold:

1. For each literal \( L_{ij} \in G_i \), there exists a node \((G_n F_n T_n C_n K_n)\), \( n = i \), such that \( P(G_n) = L_{ij} \sigma_{n+1} \cdots \sigma_n \) is the selected literal on that node to apply a CQC A-rule, where \( \sigma_{n+1} \cdots \sigma_n \) is the composition of the substitutions used in the intermediate nodes.

2. For each condition \( F_{ij} \in F_i \), there exists a node \((G_n F_n T_n C_n K_n)\), \( n = i \), such that \( F_{nm} \in F_n \) is the selected condition on that node to apply a CQC B-rule and \( F_{nm} = F_{ij} \).

A CQC-derivation is said to be fair when it is either failed or open and saturated for the CQC-expansion Rules. A CQC-tree is fair if each one of its CQC-derivations (branches) is fair. Note that a finitely failed CQC-tree is always fair, but the inverse is not necessarily true.

**Lemma 5.4**

Let \( R \) be a set of deductive rules, \( G = \leftarrow L_1 \land \cdots \land L_k \) be a goal, \( F \) be a set of conditions and \( K \) be the set of constants in \( \{G_0 \} \cup F_0 \cup R \). If there exists a saturated open CQC-derivation starting from \((G_0 F_0 \circ \emptyset K)\) then \( pComp(R) \cup \{ \exists L_1 \land \cdots \land L_k \} \cup \forall F_0 \) has a model provided that \( \{G_0 \} \cup F_0 \cup R \) is safe and hierarchical.

**Theorem 5.5 (Failure Completeness)**

If \( Q_1, S, Q_2 (Q_1, S_{ic} Q_2) \) then every fair CQC-Tree rooted at \((G_0 F_0 \circ \emptyset K)\) is finitely failed provided that \( \{G_0 \} \cup F_0 \cup DR \cup S \cup Q_i \) is safe and hierarchical.

The proof is made by contradiction and may be intuitively explained as follows. If \( Q_1, S, Q_2 (Q_1, S_{ic} Q_2) \) then \( pComp(R) \cup \{ \forall IC \} \cup \{ \exists X_1 \ldots X_n q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \} \) cannot have a model. Assuming that it is true, let us suppose that we have a non-failed CQC-derivation starting from \((G_0 F_0 \circ \emptyset K)\). However, lemma 5.4 shows that this derivation would indeed construct a model for \( pComp(DR) \cup \{ \forall IC \} \cup \{ \exists X_1 \ldots X_n q_1(X_1, \ldots, X_n) \land \neg q_2(X_1, \ldots, X_n) \} \).

### 6 Decidability Results

The QC problem is undecidable for the general case of queries and databases that the CQC Method covers AHV95). One possible source of undecidability is the presence of recursively-defined derived predicates that could make the CQC Method build and test an infinite number of EDBs. In this sense, the CQC Method excludes explicitly the presence of any type of recursion as we have seen in the proofs of the failure completeness (Theorem 5.5) and the finite success soundness and completeness (Theorems 5.1 and 5.2).

Another reason for undecidability is the presence of “axioms of infinity” [BM86] or “embedded TGD’s” [Sag88]. In this case, the initial goal to attain could only be satisfied on an EDB with an infinite number of facts because each new addition of a fact to the EDB under construction triggers a condition to be repaired with another insertion on the EDB.

For this reason, the CQC Method is semidecidable for the general case, in the sense that if either there exist one or more finite EDBs for which containment does not hold or there is no EDB (finite or infinite), the CQC Method terminates according to our completeness results (Theorems 5.2 and 5.5). Nevertheless, we can not guarantee termination under the presence of infinite counterexamples.

One of the forms to assure always termination when using the CQC Method is to delimit a priori the type of schemas and queries for which it is guaranteed that infinite non-containment counterexamples never exist. It is well known that this is the case of all the different classes of conjunctive queries,
including those allowing negated EDB atoms and built-in atoms. Then, we can guarantee that our method will always terminate in these cases.

7 Related Work

This section is devoted to compare the CQC method with previous research in the field. This comparison is intended to point out that the CQC method performs containment tests for more and broader cases of queries and database schemas than previous methods (see Section 7.1.) and that it is not less efficient than other methods for those cases that they already covered (see Section 7.2.).

7.1 Queries and Database Schemas Handled by the Methods

As we have seen, the CQC method deals with queries and database schemas that include negation on IDB predicates, integrity constraints and built-in order predicates. Previous methods that deal with negated IDB subgoals can be classified in two different approaches: either they check Uniform Query Containment or they consider just restricted cases of negation.

[LS93, ST96, DS96] check Uniform QC for queries and databases with safe negated IDB atoms. The problem is that, as pointed out in [Sag88], Uniform QC (written \( Q_1 \subseteq^u Q_2 \)) is a sufficient but not necessary condition for query containment. That is, if for a given pair of queries \( Q_1 \) and \( Q_2 \) we have that \( Q_1 \subseteq^u Q_2 \), then \( Q_1 \subseteq Q_2 \). On the other hand, if the result is that \( Q_1 \subseteq^c Q_2 \), then nothing can be said about whether or not \( Q_1 \subseteq Q_2 \) holds. In contrast, we have seen that the CQC method always checks “true” query containment.

The rest of the methods that handle negation restrict the classes of queries and database schemas they are able to deal with. Thus, we have that [Ull97, WL03] consider only conjunctive queries with negated EDB predicates, while [LS95] checks containment of a datalog query in a conjunctive query with negated EDB predicates. [HMSS01] deals with negated IDB subgoals for databases with only 1-ary EDB predicates. [CDL98] cannot express simple cases of negation on IDB predicates since it is not possible to define negation in the regular expression they consider. Finally, [BEST98] admits that ‘there may also be rules defining views’. However, it provides very poor information of how IDB atoms must be handled. They only say that IDB rules are consider as integrity constraints, assuming that there is no a ‘strict separation between extensional and intensional database’. Nevertheless, it is not clear how this translation must be done if IDB rules are expressed as integrity constraints. In the field of Description Logics (DL), [DLNN97] performs subsumption checking, a similar problem to query containment, of DL concepts which allow negation to be applied only to unary IDB predicates.

7.2 Efficiency of the Proposed Techniques

To show that the CQC method is not less efficient than other methods, we select two outstanding methods, [Ull97] and [WL03], and we show by means of an example the correspondence between the procedure followed by the CQC method and the one defined in these proposals. This comparison will also to determine that in the CQC method the simple VIP may always replace the negation VIP in the presence of negated EDB predicates, without loosing completeness.

7.2.1 Comparison with [Ull97]

The procedure of [Ull97] is an adaptation of the uniform equivalence checking method of [LS93] for the class of conjunctive queries with negated EDB atoms. Conjunctive queries are those queries that do not have any literal about IDB predicates in their defining rule bodies. We show by means of an example that the CQC Method and the one in [Ull97] generate and test the same EDB to check whether a query is contained in another one.
Example 7.1

Let $Q_1$ and $Q_2$ be two queries defining the same 2-ary query predicate $p$:

\[
Q_1 = \{ p(X, Y) \leftarrow a(X, Z) \land a(Z, Y) \land \neg a(X, Y) \}\n\]

\[
Q_2 = \{ p(X, Y) \leftarrow a(X, Z) \land a(Z, Y) \land a(Z, W) \land \neg a(X, W) \}\n\]

where a fact like $a(0, 1)$ is an EDB fact that is true whenever an arc connects 0 with 1.

As stated before, the CQC Method is intended to prove that $Q_1 \not\subseteq Q_2$ is not true by constructing an EDB for which such a relationship does not hold.

Different CQC-derivations starting from $G_0 = \leftarrow p_1(X, Y) \land \neg p_2(X, Y)$ and considering all the relevant variable instantiations are partially shown in figure 7.1. Note that the CQC Method applies the Negation VIP. Since none of the CQC-derivations ends successfully, $Q_1 \not\subseteq Q_2$.

\[
X = Z = 0
T = \{a(0, 0)\}
\]

\[
X = 0, \ Z = 1
T = \{a(0, 1)\}
\]

\[
\begin{align*}
& \leftarrow a(0, Y) \land \neg a(0, Y) \land \neg p_2(0, Y) & \leftarrow a(1, Y) \land \neg a(0, Y) \land \neg p_2(0, Y) \\
& \text{A2} & \text{A2} \\
& X = Z = 0 & X = Z = 0, \ Y = 1 \\
& T_{3a} = \{a(0, 0)\} & T_{3a} = \{a(0, 0), a(0, 1)\} \\
& & T_{3b} = \{a(0, 1)\} \\
& & \text{ST}_1, \ \text{fail} \\
& & \text{ST}_2, \ \text{fail} \\
& & \text{ST}_3, \ \text{fail} \\
& & \text{ST}_4, \ \text{fail} \\
& & \text{ST}_5, \ \text{fail} \\
\end{align*}
\]

Fig. 7.1

The CQC-(sub)derivation $\text{ST}_1$, which continues with $\leftarrow \neg a(0, 0) \land \neg p_2(0, 0)$ as the goal to attain and $\{a(0, 0)\}$ as the constructed EDB by then, is shown in figure 7.2. This derivation fails mainly because the content of EDB itself cannot satisfy $p_1$ even before enforcing $p_2$ to be false, because $\neg a(0, 0)$ cannot be made false with $\{a(0, 0)\}$. $\text{ST}_2$ and $\text{ST}_3$ fail in a similar way for the same reason.
described in [Ull97]:

2) false.

e.g. Fig. 7.2

Table 7.1 summarizes the steps followed to check that (0, 1), (0, 2) is true, is constructed, the CQC-derivation fails because (0, 2) is attempted to be made false by adding (0, 2), but such an inclusion would also make (0, 2) false. ST₃ fails in a similar way for the same reason.

Fig. 7.2

The CQC-(sub)derivation ST₃, which continues with \( \leftarrow \neg a(0, 2) \land \neg p₂(0, 2) \) as the goal to satisfy and \( \{a(0, 1), a(1, 2)\} \) as the constructed EDB by then, is shown in figure 7.3. Although an EDB satisfying \( p₁ \), e.g. \( p₁(0, 2) \) is true, is constructed, the CQC-derivation fails because \( p₂(0, 2) \) cannot be made false. Note that \( p₂(0, 2) \) is attempted to be made false by adding \( a(0, 2) \), but such an inclusion would also make \( p₁(0, 2) \) false. ST₃ fails in a similar way for the same reason.

Fig. 7.3.

Table 7.1 summarizes the steps followed to check that \( Q₁ \subseteq Q₂ \) holds according to the procedure described in [Ull97]:

1. Construct the set of basic canonical EDBs that correspond to all the partitions of the set of variables in \( Q₁ \). For each variable partition, define a variable substitution \( σ_i \) that assigns a unique constant to each block of the partition. For each resultant \( σ_i \), construct a canonical database by applying \( σ_i \) to the positive atoms of the \( Q₁ \) rule body. In this example, a canonical EDB is obtained for each one of the five possible partitions of the variables \( X, Z \), and \( Y \) from \( Q₁ \).

2. For each canonical EDB \( CD_i \), check that if \( Q₁(CD_i) \) contains the frozen head of \( Q₁, p(X, Y)σ_i \), then so does \( Q₂(CD_i) \). On \( CD₁ \), \( CD₂ \) and \( CD₃ \), \( p(X, Y)σ_i \) does not hold for \( Q₁ \) because the negative literal \( \neg a(X, Y) \) becomes false according to \( σ_i \), i.e. \( a(X, Y)σ_i \) is true. These three \( CD_i \) are discarded for the following steps.

3. For the remaining canonical EDBs, \( CD₄ \) and \( CD₅ \), construct the set of extended canonical EDBs, \( ECD₄ \) and \( ECD₅ \), by adding to these \( CD_i \) other ground facts about \( A \) formed from all possible
combinations with the constant values in \( \sigma \), but not these ones that would make \( a(X, Y) \sigma \) true. For instance, \( a(1, 1) \) but not \( a(0, 0) \) has been added to \( ECD_s \).

4. For \( ECD_1 \) and \( ECD_5 \), check that if \( Q_1(ECD) \) contains \( p(X, Y) \sigma \), then so does \( Q_2(ECD) \). In this case, it is true for the two extended canonical EDBs and it proves that \( Q_1 \not\subseteq Q_2 \) is true (see [Ull97, LS93] for more details).

It is easy to see that there is a clear correspondence between the CQC Method and the procedure described in [Ull97] for this example. In particular, looking at figure 7.1, it can be noticed that each EDB constructed at the \( 3^{rd} \)-level steps of the CQC-derivations correspond to one of the canonical EDBs build at the \( 1^{st} \) step of table 7.1. Moreover, CQC-derivations \( ST_1, ST_2 \) and \( ST_3 \) fail because \( \neg a(X, Y) \sigma \) is false and it makes \( p_1(X, Y) \sigma \) be false too, as it happens when \( Q_1 \) is evaluated on canonical EDBs \( CD_1, CD_2 \) and \( CD_3 \), step 2 in table 7.1. In addition, the CQC-derivations for \( ST_3 \) and \( ST_5 \) correspond to the steps 2-4 followed for the canonical EDBs \( CD_3 \) and \( CD_5 \), respectively. In particular, both methods use the concept of \( eXtended \) EDBs, but in a slightly different way. [Ull97] extends their canonical EDBs by adding new facts that keep \( p_1(X, Y) \sigma \) true to check if \( p_1(X, Y) \sigma \), still holds. In contrast, since the CQC Method wants to prove the non-containment relationship, it tries to extend \( T \) by adding a new fact that will make \( p_1(X, Y) \sigma \) be false. However, such an addition also makes \( p_1(X, Y) \sigma \), false, and thus, it cannot be performed. Therefore, \( ST_3 \) and \( ST_5 \) fail while \( p_2(X, Y) \sigma \), still holds on \( ECD_3 \) and \( ECD_5 \).

</table>

The previous comparison illustrates that both the CQC Method and the algorithm of [Ull97] achieve the same results for conjunctive queries with negated EDB atoms, but their strategies are different. The CQC builds and tests canonical EDBs dynamically since it finds one that fulfills the initial goal to attain or since no canonical EDB, with or without extension, satisfies the goal after having built all. Instead, the method of [Ull97] first builds all the canonical EDBs and then, it tests if each of them accomplishes the containment relationship. However, this latter approach is not intended to be used when there are derived literals in the bodies of the rules that define the queries.

Finally, the approach of [Ull97] can be easily extended to consider order predicates in the rule bodies of conjunctive queries over the two types of interpretations, dense or discrete. In this case, the canonical databases that would be built in step 1 of the algorithm should take into account every possible total ordering of variables appearing in \( Q_1 \). Again, the CQC Method not only covers this class of queries but also constructs similar (canonical) EDBs.

### 7.2.2 Comparison with [WL03]

The algorithm proposed in [WL03] to check conjunctive query containment with safe negated EDB atoms improves efficiency of [Ull97] because it is able to prove either \( Q_1 \subseteq Q_2 \) or \( Q_1 \not\subseteq Q_2 \) without generating
necessarily the complete set of canonical EDBs that the method of [ULI97] needs to construct. We apply the theoretical results in which this algorithm is based to show that the Simple VIP may replace the Negation VIP when using the CQC Method to check QC for conjunctive queries with negated EDB atom, without any loss of completeness. Applying the Simple VIP we do not to generate all the canonical EDBs that the Negation VIP and [ULI97] would consider to prove \( Q_1 \subseteq Q_2 \) and we can conclude that the CQC method + Simple VIP is as efficient as the algorithm in [WL03] for the cases covered by this method.

Let \( Q_1 \) and \( Q_2 \) be two conjunctive queries with negated EDB atoms:

\[
Q_1 = \{ q(X) \leftarrow p_1(X_1) \land \ldots \land p_n(X_n) \land \neg s_1(Y_1) \land \ldots \land \neg s_m(Y_m) \}
\]

\[
Q_2 = \{ q(U) \leftarrow r_1(U_1) \land \ldots \land r_n(U_n) \land \neg t_1(W_1) \land \ldots \land \neg t_k(W_k) \}
\]

According to [WL03, Theorem 2], \( Q_1 \subseteq Q_2 \) if and only if the following two conditions get satisfied:

1. There is a containment mapping \( ? \) from \( Q_2^+ \) to \( Q_1^+ \) such that \( Q_1^+ \subseteq Q_2^+ \), where

\[
Q_1^+ = \{ q(X) \leftarrow p_1(X_1) \land \ldots \land p_n(X_n) \}
\]

\[
Q_2^+ = \{ q(U) \leftarrow r_1(U_1) \land \ldots \land r_n(U_n) \}
\]

2. For each \( j, \ 1 \leq j \leq k \), \( P_j \subseteq Q_2 \) holds, where

\[
P_j = \{ q(X) \leftarrow p_1(X_1) \land \ldots \land p_n(X_n) \land ?(t_j(W_j)) \land \neg s_1(Y_1) \land \ldots \land \neg s_m(Y_m) \}
\]

Notice that this result has an intrinsic recursive structure: each test for \( P_j \subseteq Q_2 \) may require re-evaluating the two conditions just defined. There are two base cases that stop recursion. The first one occurs when \( P_j \) is unsatisfiable since \( ?(t_j(W_j)) = \neg s_i(Y_i) \), for some \( i, \ 1 \leq i \leq m \). Consequently, \( P_j \subseteq Q_2 \) holds trivially. The second base case occurs when \( P_j \subseteq Q_2 \) since for each \( P_j \) being a containment mapping from \( Q_2^+ \) to \( P_j^+ \) there exists at least one \( g, 1 \leq g \leq k \), such that \( p_i(h_i(W_i)) \in \{ p_1(X_1), \ldots, p_n(X_n), ?(t_j(W_j)) \} \) [WL03, Theorem 1]. When this latter occurs, \( Q_1 \subseteq Q_2 \).

In the previous section, example 7.1 helped to show that the CQC Method + Negation VIP operates similarly than the method of [ULI97] when checking conjunctive query containment with negated EDB atoms. Now, the same example will help to grasp these new results from [WL03] as well as to show how they are applied inherently by the CQC Method + Simple VIP.

**Example 7.2**

Recall \( Q_1 \) and \( Q_2 \) being two queries defining the same 2-ary query predicate \( p \):

\[
Q_1 = \{ p(X, Y) \leftarrow a(X, Z) \land a(Z, Y) \land \neg a(X, Y) \}
\]

\[
Q_2 = \{ p(X, Y) \leftarrow a(X, Z) \land a(Z, Y) \land a(Z, W) \land \neg a(X, W) \}
\]

where \( a \) is, of course, an EDB relation.

In this example, there is just one containment mapping from \( Q_2^+ \) to \( Q_1^+ \) which proves \( Q_1^+ \subseteq Q_2^+ \):

\[
? = \{ X_{Q_2} \rightarrow X_{Q_1}, Y_{Q_2} \rightarrow Y_{Q_1}, Z_{Q_2} \rightarrow Z_{Q_1}, W_{Q_2} \rightarrow Y_{Q_1} \},
\]

According to [WL03, Theorem 2] only one of all possible containment mappings suffices to accomplish the second condition of the theorem. Obviously, any algorithm claiming completeness must systematically test all containment mappings before concluding that none is the “elected” one. Nevertheless, in this example it is enough to explore just one alternative and not many of them. Moreover, since \( Q_2 \) only contains a negated atom, \( \neg a(X, W) \), only one new conjunctive query \( P_1 \) needs to be generated:

\[
P_1 = \{ p(X, Y) \leftarrow a(X, Z) \land a(Z, Y) \land a(X, Y) \land \neg a(X, Y) \}
\]

where \( a(X_{Q_1}, Y_{Q_1}) \) comes from \( \neg a(X_{Q_2}, W_{Q_2})) \).

Clearly, \( P_1 \) is unsatisfiable since it contains both \( a(X, Y) \) and \( \neg a(X, Y) \) and, thus, it computes no answer in any database. Consequently, \( P_1 \subseteq Q_2 \), so \( Q_1 \subseteq Q_2 \).
Now, consider again the CQC-derivation depicted partially in figure 7.1 as the most-right branch in the CQC-Tree sketched there, and then concluded in figure 7.3. This derivation introduces a new constant each time that a distinct variable requires to be instantiated, so it can be thought of implementing the Simple VIP. In fact, constructing and then testing a canonical EDB with the Simple VIP is an indirect method to find out containment mappings.

In this way, steps 2b and 3bc in the CQC-tree shown in figure 7.1 construct a canonical EDB for $Q_1^+$ according to the Simple VIP: $\{a(0, 1), a(1, 2)\}$. Conversely, steps 8bc, 9bc and 10bc in figure 7.3 successfully match the atoms in $Q_2^+$ with the constructed EDB, so the containment mapping $? \rightarrow \{X_1^1 \rightarrow 0 \rightarrow X_2^1, Y_1^1 \rightarrow 2 \rightarrow Y_2^1, Z_1^1 \rightarrow 1 \rightarrow Z_2^1, W_1^1 \rightarrow 2 \rightarrow Y_2^1\}$.

The second part of the test, that is, whether $P_1 \leq Q_2$ holds, can also be tracked easily on the CQC-derivation in figure 7.3. The generation itself of the new query $P_1$ by adding $? = a(X_2^2, W_2^2) = a(X_1^1, Y_1^1)$ to the body of $Q_1$ has its “CQC-counterpart” in the addition of $a(0, 2) = a(X_2^2, W_2^2)\{X_2^2\{0, W_2^2\}\} = \{X_2^2\{0, W_2^2\}\}$ to the goal part, in step 11bc, which was “inhabited” previously by the atoms coming from the body of $Q_1$. The unsatisfiability of $P_1$ is detected as soon as $a(0, 2)$ is added to the EDB and condition $C_1$ is triggered and evaluated. Notice that the EDB constructed by then is nothing but the “frozen” body of $P_1^+$. Moreover, if $P_1$ had not been unsatisfiable then the triggering and later evaluation of condition $C_2 = \leftarrow a(0, Z) \wedge a(Z, 2) \wedge a(Z, W) \wedge \neg a(X, W)$ would have determined whether there existed a containment mapping from $Q_2^+$ to $P_1^+$ in order to prove $P_1^+ \leq Q_2^+$ as a first step towards proving $P_1 \leq Q_2$.

8 Conclusions

In this paper we have presented the Constructive Query Containment (CQC) method for QC Checking which checks "true" QC and QcQC for queries over databases with safe negation in both IDB and EDB subgoals and with or without built-in predicates. As far as we know, ours is the first proposal that covers all these features in a single method and in a uniform and integrated way.

We have proved several properties regarding the correctness of the CQC method: finite success soundness for hierarchical queries and databases, failure soundness, finite success completeness for strict-stratified queries and databases and failure completeness for hierarchical queries and databases. From these results, and from previous results that showed that infinite non-containment counterexamples never exist in the particular case of checking QC for conjunctive queries with safe EDB negation and built-in predicates, we can ensure termination, and thus decidability, of our method for those cases.

The main contributions of this paper are twofold. First, we have shown that the CQC method performs containment tests for more and broader cases of queries and database schemas than previous methods. Second, we have also shown that the CQC method is decidable and not less efficient than other methods to check query containment of conjunctive queries with or without safe negated EDB predicates.

As a further work we plan to characterize other classes of queries and deductive rules for which our method always terminates.

References

Appendix A: Variable Instantiation Procedure

A variable instantiation procedure from \( \{X_1, X_2, \ldots, X_n\} \theta_0, K_0 \) to \( (\emptyset \theta, K) \) is a sequence \( \{X_1, X_2, \ldots, X_n\} \theta_1, K_1, \ldots, (\emptyset \theta, K_n) \) such that for each \( 0 = i = n, \theta_i \) is a ground substitution and \( K_i \) is a set of constants.

A variable instantiation step performs a transition from \( \langle X_i, \theta_i, K_i \rangle \) to \( \langle X_{i+1}, \theta_{i+1}, K_{i+1} \rangle \) that instantiates the variable \( X_{i+1} \) of \( X_i \) according to one of the VIP-rules defined by selected variable instantiation pattern (VIP). The application of the appropriate VIP to a given class of queries and databases ensures the completeness of the CQC method with respect to that class.

The formalization of the VIP-rules is given below. We denote constants as \( k, k_{\text{new}} \) and \( k, \text{max} \) and \( \text{min} \) are two functions that range over sets of constants and they return the constants having the greatest value and the least value, respectively, of those sets.

**VIP-rule for the Simple VIP**

\[
S. \ X_{i+1} = \tilde{X}_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup k_{\text{new}} \text{, where } k_{\text{new}} \notin K_i.
\]

**VIP-rules for the Negation VIP**

- N1. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k\} \text{ and } K_{i+1} = K_i \), where \( k \in K_i \).
- N2. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup k_{\text{new}} \text{, where } k_{\text{new}} \notin K_i. \)

**VIP-rules for the Dense Order VIP**

- Den1. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k\} \text{ and } K_{i+1} = K_i \), where \( k \in K_i \).
- Den2. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup k_{\text{new}} \text{, where } k_{\text{new}} < \text{min}(K_i). \)
- Den3. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup k_{\text{new}} \text{, where } k_i < k_{\text{new}} < k_{j+1}, \{k_i, k_{j+1}\} \subseteq K_i \text{ and there is no } k \in K_i \text{ such that } k_i < k < k_{j+1}. \)
- Den4. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup k_{\text{new}} \text{, where } \text{max}(K_i) < k_{\text{new}}. \)

**VIP-rules for the Discrete Order VIP**

The formalization of the rules for this VIP requires supplementary definitions. A virtual constant [NSS98] is a discrete constant whose value is not determined by a numeric quantity but by its relative position in a linear ordering of constants. Let from now on static constant stand for a discrete constant that is not a virtual constant. We explicitly denote virtual constants as \( \text{c}_i, \text{c}_{\text{min}} \) and \( \text{c}_{\text{max}} \). Select and apply one of the following six rules:

- Dis1. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/k\} \text{ and } K_{i+1} = K_i \), where \( k \in K_i \).
- Dis2. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/d_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup d_{\text{new}} \text{, where } d_{\text{new}} \text{ is a new virtual constant such that } d_{\text{new}} < \text{min}(K_i). \)
- Dis3. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/d_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup d_{\text{new}} \text{, where } d_{\text{new}} \text{ is a new virtual constant s.t.} \)
- \( \text{min}(K_i) = d < d_{\text{new}} < k_{j+1} = c_{\text{min}} \{d_j, k_{j+1}, c_{\text{min}}\} \subseteq K_i \text{, there is no virtual constant } d_k \in K_i \text{ such that } d < d_k < k_{j+1} \text{ and there is no static constant } c_p \in K_i \text{ such that } c_p < c_{\text{min}}. \)
- Dis4. \( \bar{X}_{i+1} = \bar{X_i} \backslash X_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/d_{\text{new}}\} \text{ and } K_{i+1} = K_i \cup d_{\text{new}} \text{, where } d_{\text{new}} \text{ is a new virtual constant s.t.} \)
- \( c_j = k_j < d_{\text{new}} < k_{j+1} = c_{\text{min}} \{c_j, k_j, k_{j+1}, c_{\text{min}}\} \subseteq K_i \text{, there is no virtual constant } d_k \in K_i \text{ such that } k_j < d_k < k_{j+1}, \)
there is no static constant \( c_p \in K \) such that \( c_j < c_p < c_{j+1} \) and
\[
|\{d_q \mid d_q \in K_i \text{ and } c_j < d_q < c_{j+1}\}| < |c_{j+1} - c_j| - 1
\]

Dis5. \( \bar{X}_{i+1} = \bar{X}_i \setminus \bar{X}_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/d_{\text{new}}\} \) and \( K_{i+1} = K_i \cup \{d_{\text{new}}\} \), where \( d_{\text{new}} \) is a new virtual constant s.t.
\[
- \ c_{\text{max}} = k_j < d_{\text{new}} < d_{j+1} = \max(K_i), \ {c_{\text{max}}, k_j, d_{j+1}} \subseteq K_i,
- \ there is no virtual constant \( d_h \in K_i \) such that \( k_j < d_h < d_{j+1} \) and
- \ there is no static constant \( c_p \in K_i \) such that \( c_{\text{max}} < c_p \)

\( \bar{X}_{i+1} = \bar{X}_i \setminus \bar{X}_{i+1}, \theta_{i+1} = \theta_i \cup \{X_{i+1}/d_{\text{new}}\} \) and \( K_{i+1} = K_i \cup \{d_{\text{new}}\} \), where \( d_{\text{new}} \) is a new \textit{virtual} constant such that
\[
\max(K_i) < d_{\text{new}}.
\]
