A coagulum is the final product of the blood coagulation step in hemostasis. It is achieved via the aggregation of platelets that form a platelet plug, and the activation of the humoral coagulation system. A coagulum is normal in cases of injury.

Specifically, a coagulum is the inappropriate activation of the hemostatic process in an uninjured or slightly injured vessel. A coagulum in a large blood vessel will decrease blood flow through that vessel. In a small blood vessel, blood flow may be completely cut-off resulting in death of tissue supplied by that vessel.
