## Introduction

The aim of this work is to provide asymptotic estimates for the splitting of separatrices in a perturbed 3-degree-of-freedom Hamiltonian system, associated to a 2-dimensional whiskered torus (invariant hyperbolic torus) whose frequency ratio is a quadratic irrational number. We show that the dependence of the asymptotic estimates on the perturbation parameter is described by some functions which satisfy a periodicity property, and whose behavior depends strongly on the arithmetic properties of the frequencies.

First, we describe the Hamiltonian system to be studied. It is also considered in [6], as a generalization of the famous Arnold’s example [1], and provides a model for the behavior of a nearly-integrable Hamiltonian system in the vicinity of a single resonance (see [3] for a motivation). In canonical coordinates  $(x, y, \varphi, I) \in \mathbb{T} \times \mathbb{R} \times \mathbb{T}^2 \times \mathbb{R}^2$ , we consider a perturbed Hamiltonian

$$(1) \quad H(x, y, \varphi, I) = H_0(x, y, I) + \mu H_1(x, \varphi).$$

$$(2) \quad H_0(x, y, I) = \langle \omega_\varepsilon, I \rangle + \frac{1}{2} \langle \Lambda I, I \rangle + \frac{y^2}{2} + \cos x - 1,$$

$$(3) \quad H_1(x, \varphi) = \cos x \cdot \sum_{k_2 \geq 0} e^{-\rho|k|} \cos(\langle k, \varphi \rangle - \sigma_k).$$

For the integrable Hamiltonian  $H_0$ , we consider a vector of *fast frequencies*

$$(4) \quad \omega_\varepsilon = \frac{\omega}{\sqrt{\varepsilon}}, \quad \omega = (1, \Omega),$$

where the frequency ratio  $\Omega$  is a *quadratic* irrational number. In this way, our system has two parameters  $\varepsilon > 0$  and  $\mu$ , but we assume them linked by a relation of kind  $\mu = \varepsilon^p$ ,  $p > 0$  (the smaller  $p$  the better). Thus, if we consider  $\varepsilon$  as the unique parameter, we have a *singular* or *weakly hyperbolic* problem for  $\varepsilon \rightarrow 0$  (see [3] for a discussion about singular and regular problems).

On the other hand, notice that  $H_0$  consists of a classical pendulum and 2 rotors (in the coordinates  $x, y$  and  $\varphi, I$  respectively). Then, we see that  $H_0$  has a family of

2-dimensional whiskered tori, with coincident whiskers (invariant manifolds). Such tori can be indexed by the (constant) action  $I$ , and have frequency vectors  $\omega_\varepsilon + \Lambda I$ . We assume that the matrix  $\Lambda$  is such that the condition of *isoenergetic nondegeneracy* is satisfied (see for instance [6]). Among the tori, we fix our attention on the torus given by  $I = 0$ ,

$$\mathcal{T}_0 : \quad (0, 0, \theta, 0), \quad \theta \in \mathbb{T}^2,$$

whose inner flow is given, in this parameterization, by  $\dot{\theta} = \omega_\varepsilon$ . This torus has a homoclinic whisker (i.e. coincident stable and unstable whiskers),

$$\mathcal{W}_0 : \quad (x_0(s), y_0(s), \theta, 0), \quad s \in \mathbb{R}, \theta \in \mathbb{T}^2,$$

where  $x_0(s) = 4 \arctan e^s$ ,  $y_0(s) = 2/\cosh s$  (the upper separatrix of the classical pendulum). The inner flow on  $\mathcal{W}_0$  is given by  $\dot{s} = 1$ ,  $\dot{\theta} = \omega_\varepsilon$ .

Concerning the perturbation  $H_1$ , it is given by a constant  $\rho > 0$  (the complex width of analyticity in the angles  $\varphi$ ), and phases  $\sigma_k$  that, for the purpose of this work, can be chosen arbitrarily.

Under the hypotheses described, the *hyperbolic KAM theorem* (see for instance [8]) can be applied to the perturbed Hamiltonian (1–3). We have that, for  $\mu \neq 0$  small enough, the whiskered torus  $\mathcal{T}_0$  persists with some shift and deformation giving rise to a perturbed torus  $\mathcal{T}$ , with perturbed local stable and unstable whiskers.

Such local whiskers can be extended to global whiskers  $\mathcal{W}^s, \mathcal{W}^u$  but, in general, for  $\mu \neq 0$  they do not coincide anymore, and one can introduce a *splitting function* giving the distance between the whiskers in the directions of the actions  $I \in \mathbb{R}^2$ : denoting  $\mathcal{J}^{s,u}(\theta)$  parameterizations of a transverse section of both whiskers, one can define  $\mathcal{M}(\theta) := \mathcal{J}^u(\theta) - \mathcal{J}^s(\theta)$ ,  $\theta \in \mathbb{T}^2$ . In fact, this function turns out to be the gradient of the (scalar) *splitting potential*:  $\mathcal{M}(\theta) = \nabla \mathcal{L}(\theta)$  (see [2, §5.2], and also [7]).

In (4), we deal with the following 24 quadratic numbers

$$(5) \quad [\overline{1}], [\overline{2}], \dots, [\overline{13}], [\overline{1,2}], \dots, [\overline{1,12}],$$

where we denote a quadratic number according to its periodic part in the continued fraction (see (8)).

Next, we establish the *main result* of this work, providing two types of *asymptotic estimates* for the splitting, as  $\varepsilon \rightarrow 0$ . On one hand, we give an estimate for the *maximal splitting distance*, i.e. for the maximum of  $|\mathcal{M}(\theta)|$ ,  $\theta \in \mathbb{T}^2$ . On the other hand, we show that for most values of  $\varepsilon \rightarrow 0$  there exist 4 transverse homoclinic orbits, associated to simple zeros  $\theta_*$  of  $\mathcal{M}(\theta)$  (i.e. nondegenerate critical points of  $\mathcal{L}(\theta)$ ) and, for such homoclinic orbits, we obtain an estimate for the *transversality* of the splitting, given by the minimum eigenvalue (in modulus) of the matrices  $D\mathcal{M}(\theta_*)$ .

We use the notation  $f \sim g$  if we can bound  $c_1|g| \leq |f| \leq c_2|g|$  with positive constants  $c_1, c_2$  not depending on  $\varepsilon, \mu$ .

**Theorem 1** *Assume the conditions described above for the Hamiltonian (1–3), and that  $\varepsilon$  is small enough and  $\mu = \varepsilon^p$ ,  $p > 3$ . Then, there exist continued functions  $h_1(\varepsilon)$  and  $h_2(\varepsilon)$  (defined in (17)), periodic in  $\ln \varepsilon$  and satisfying  $1 \leq h_1(\varepsilon) \leq h_2(\varepsilon)$ , and a positive constant  $C_0$  (given in (16)), such that:*

(a) *for the maximal splitting distance, we have the estimate*

$$\max_{\theta \in \mathbb{T}^2} |\mathcal{M}(\theta)| \sim \frac{\mu}{\sqrt{\varepsilon}} \exp \left\{ -\frac{C_0 h_1(\varepsilon)}{\varepsilon^{1/4}} \right\};$$

- (b) the splitting function  $\mathcal{M}(\theta)$  has exactly 4 zeros  $\theta_*$ , all simple, for all  $\varepsilon$  except for a small neighborhood of a finite number of geometric sequences of  $\varepsilon$ ;
- (c) at each zero  $\theta_*$  of  $\mathcal{M}(\theta)$ , the minimal eigenvalue of  $D\mathcal{M}(\theta_*)$  satisfies

$$m_* \sim \mu \varepsilon^{1/4} \exp \left\{ -\frac{C_0 h_2(\varepsilon)}{\varepsilon^{1/4}} \right\}.$$

For the proof of this theorem, we apply the *Poincaré–Melnikov method*, which provides a first order approximation

$$(6) \quad \mathcal{M}(\theta) = \mu \nabla L(\theta) + \mathcal{O}(\mu^2)$$

in terms of the *Melnikov potential*, which can be defined by integrating the perturbation  $H_1$  along the trajectories of the unperturbed homoclinic whisker  $\mathcal{W}_0$ :

$$(7) \quad L(\theta) := - \int_{-\infty}^{\infty} H_1(x_0(t), \theta + \omega_\varepsilon t) dt.$$

Since this first order approximation is exponentially small in  $\varepsilon$ , in principle the approximation (6) cannot be directly applied in our singular problem with  $\mu = \varepsilon^p$ . However, using suitable bounds for the error term  $\mathcal{O}(\mu^2)$ , given in [6], one can see that for  $p > 3$  the first order approximation given by the Melnikov potential overcomes the error term and provides the right asymptotic estimates for the splitting. Such estimates come from the size of *dominant harmonics* in the Fourier expansion of (7), and studying their dependence on  $\varepsilon$ . More precisely, to estimate the maximal splitting one dominant harmonic is enough and, to estimate the transversality of the splitting, two dominant harmonics are required (excluding the values of  $\varepsilon$  such that the second and third harmonics are of the same magnitude, which could give rise to bifurcations in the homoclinic orbits and would require a further study).

The remaining sections of this work are devoted to the definition of the functions  $h_1(\varepsilon)$  and  $h_2(\varepsilon)$ , putting emphasis on their dependence on the arithmetic properties of the quadratic number  $\Omega$ .

## Continued fractions and resonant sequences

We review briefly the technique developed in [4] for studying the resonances of quadratic frequencies. Let  $0 < \Omega < 1$  be a quadratic irrational number. It is well-known that it has an infinite continued fraction

$$(8) \quad \Omega = [a_1, a_2, a_3, \dots] = \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots}}}, \quad a_n \in \mathbb{Z}^+, \quad n \geq 1 \quad (\text{and } a_0 = 0),$$

that is that is *eventually periodic*, i.e., periodic starting at some  $a_l$ . For a purely  $m$ -periodic continued fraction  $\Omega = [\overline{a_1, \dots, a_m}]$  we introduce the matrix

$$U = (-1)^m A_1^{-1} \cdots A_m^{-1}, \quad \text{where } A_l = \begin{pmatrix} a_l & 1 \\ 1 & 0 \end{pmatrix}, \quad l = 1, \dots, m.$$

It is well-known that quadratic vectors satisfy a *Diophantine condition*

$$|\langle k, \omega \rangle| \geq \frac{\gamma}{|k|}, \quad \forall k \in \mathbb{Z}^2 \setminus \{0\}.$$

With this in mind, we define the “numerators”

$$(9) \quad \gamma_k := |\langle k, \omega \rangle| \cdot |k|, \quad k \in \mathbb{Z}^2 \setminus \{0\}$$

(for integer vectors, we use the norm  $|\cdot| = |\cdot|_1$ ). Our aim is to find the integer vectors  $k$  which give the smallest values  $\gamma_k$ , we call such vectors  $k$  the *primary resonances*.

All vectors  $k \in \mathbb{Z}^2 \setminus \{0\}$  with  $|\langle k, \omega \rangle| < 1/2$  are subdivided into *resonant sequences*:

$$(10) \quad s(j, n) := U^n k^0(j), \quad n = 0, 1, 2, \dots$$

where the initial vector  $k^0(j) = (-\text{rint}(j\Omega), j)$ ,  $j \in \mathbb{Z}^+$ , satisfies

$$(11) \quad \frac{1}{2\lambda} < |\langle k^0(j), \omega \rangle| < \frac{1}{2},$$

$\lambda$  being the eigenvalue of  $U$  with  $\lambda > 1$ . For each  $j \in \mathbb{Z}^+$  satisfying (11), it was proved in [4, Th. 2] (see also [5]) that, asymptotically, the resonant sequence  $s(j, n)$  exhibits a geometric growth and the sequence  $\gamma_{s(j, n)}$  has a limit  $\gamma_j^*$ :

$$(12) \quad |s(j, n)| = K_j \lambda^n + \mathcal{O}(\lambda^{-n}), \quad \gamma_{s(j, n)} = \gamma_j^* + \mathcal{O}(\lambda^{-2n}), \quad \text{as } n \rightarrow \infty,$$

where  $K_j$  and  $\gamma_j^*$  can be determined explicitly for each resonant sequence (see explicit formulas in [4]). We select the minimal of  $\gamma_j^*$ :

$$(13) \quad \gamma^* := \liminf_{|k| \rightarrow \infty} \gamma_k = \min_j \gamma_j^* = \gamma_{j_0}^* > 0.$$

The integer vectors of the corresponding sequence  $s(j_0, n)$  are the *primary resonances*, and we call the *secondary resonances* the integer vectors belonging to any of the remaining resonant sequences  $s(j, n)$ ,  $j \neq j_0$ . We also call by the *main secondary resonances* the sequence  $s(j_1, n)$  which is linearly independent with  $s(j_0, n)$  and gives the smallest limit  $\gamma_{j_1}^*$  among the secondary resonances.

### The functions $h_1(\varepsilon)$ and $h_2(\varepsilon)$

Taking into account the form of  $H_1$  in (3), we present the Melnikov potential (7) in its Fourier expansion. Using (4) and (9), we present the coefficients in the form

$$(14) \quad L_k = \frac{2\pi |\langle k, \omega_\varepsilon \rangle| e^{-\rho|k|}}{\sinh |\frac{\pi}{2} \langle k, \omega_\varepsilon \rangle|} = \alpha_k e^{-\beta_k}, \quad \alpha_k \approx \frac{4\pi \gamma_k}{|k| \sqrt{\varepsilon}}, \quad \beta_k = \rho|k| + \frac{\pi \gamma_k}{2|k| \sqrt{\varepsilon}}.$$

For any given  $\varepsilon$ , we find the dominant harmonics  $L_k(\varepsilon)$  which correspond essentially to the smallest exponents  $\beta_k(\varepsilon)$ .

The exponents  $\beta_k(\varepsilon)$  in (14) can be presented in the form

$$(15) \quad \beta_k(\varepsilon) = \frac{C_0}{\varepsilon^{1/4}} g_k(\varepsilon), \quad g_k(\varepsilon) := \frac{\tilde{\gamma}_k^{1/2}}{2} \left[ \left( \frac{\varepsilon}{\varepsilon_k} \right)^{1/4} + \left( \frac{\varepsilon_k}{\varepsilon} \right)^{1/4} \right],$$

where

$$(16) \quad \varepsilon_k := D_0 \frac{\tilde{\gamma}_k^2}{|k|^4}, \quad \tilde{\gamma}_k = \frac{\gamma_k}{\gamma^*}, \quad C_0 = (2\pi \rho \gamma^*)^{1/2}, \quad D_0 = \left( \frac{\pi \gamma^*}{2\rho} \right)^2.$$

Since the coefficients  $L_k$  are exponentially small in  $\varepsilon$ , it is more convenient to work with the functions  $g_k$ , whose smallest values correspond to the largest  $L_k$ . To this aim, it is useful to consider the graphs of the functions  $g_k(\varepsilon)$ ,  $k \in \mathbb{Z}^2 \setminus \{0\}$ , in order to detect the minimum of them for a given value of  $\varepsilon$ .

We know from (15) that the functions  $g_k(\varepsilon)$  have their minimum at  $\varepsilon = \varepsilon_k$  and the corresponding minimal values are  $g_k(\varepsilon_k) = \tilde{\gamma}_k^{1/2}$ . For the integer vectors  $k = s(j, n)$  belonging to a resonant sequence (10), using the approximations (12), we have

$$\varepsilon_{s(j,n)} \approx \frac{D_0(\tilde{\gamma}_j^*)^2}{K_j^4 \lambda^{4n}}, \quad g_{s(j,n)}(\varepsilon) \approx \frac{(\tilde{\gamma}_j^*)^{1/2}}{2} \left[ \left( \frac{\varepsilon}{\varepsilon_{s(j,n)}} \right)^{1/4} + \left( \frac{\varepsilon_{s(j,n)}}{\varepsilon} \right)^{1/4} \right], \quad \text{as } n \rightarrow \infty.$$

Taking into account such approximations, we have a periodic behavior of the functions with respect to  $\ln \varepsilon$ , as we see in Figure 1 (where a logarithmic scale for  $\varepsilon$  is used).

We define, for any given  $\varepsilon$ , the function  $h_1(\varepsilon)$  and  $h_2(\varepsilon)$  as

$$(17) \quad h_1(\varepsilon) := \min_k g_k(\varepsilon) = g_{S_1}(\varepsilon), \quad h_2(\varepsilon) := \min_{k \text{ lin.indep. of } S_1} g_k(\varepsilon) = g_{S_2}(\varepsilon),$$

with some integer vectors  $S_1(\varepsilon)$  and  $S_2(\varepsilon)$  realizing such minima. The functions are continuous and  $4 \ln \lambda$ -periodic in  $\ln \varepsilon$ . It turns out that for the 24 quadratic numbers (5), the integer vector  $S_1(\varepsilon)$  providing  $h_1(\varepsilon)$  always corresponds to a primary resonance, defined in (13). On the other hand, the vector  $S_2(\varepsilon)$  providing  $h_2(\varepsilon)$  may correspond to primary or main secondary resonances in different intervals of  $\varepsilon$  (see Figure 1 for an illustration for the number  $[\overline{1, 2}] = \sqrt{3} - 1$ ). There is a finite number of geometric sequences of  $\varepsilon$ , where a change in  $S_2(\varepsilon)$  occurs. These points require a special study for the transversality and they are excluded in Theorem 1.
